Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

GENERAL

5628 EFFECTS OF CATIONS ON ILEAL COMPLIANCE AND BLOOD FLOW. (E.) Dabney, J. M. (Michigan State U., East Lansing), J. B. Scott and C. C. Chou. Amer. J. Physiol. 212(4): 835-839, 1967.

The action of a local intra-arterial infusion of KCl, $MgCl_2$ and $CaCl_2$ on vascular resistance and intestinal wall compliance was studied in ileal segments of the anesthetized dog. With collateral flow excluded, either venous outflow was measured or arterial inflow was controlled with a pump. Intestinal compliance (compliance defined as Δ lumen vol./Δ lumen pressure) was studied only in the pump-perfused experiments by distending the ileal lumen and recording the pressure developed. In experiments measuring venous outflow, Mg increased, K had a biphasic action and the action of Ca on flow was irregular but, on the av., not significant. K alone significantly affected lumen pressure. Study of intestinal compliance during infusion of these ions showed that Ca and Mg increased compliance, but K had a biphasic action depending upon the rate of infusion. These results support the theory that the total effect of these cations on intestinal vascular resistance is mediated through their action on both vascular and intestinal smooth muscle.

5629 STUDIES ON INTESTINAL CIRCULATION. (E.) Wallentin, I. (U. Goteborg, Sweden). Acta Physiol. Scand. 69(Suppl. 279): 1-38, 1966.

The intestinal vascular bed in cats was studied during a max. range of induced changes in vascular tone produced either by pharmacological agents or by stimulation of sympathetic vasoconstrictor fibers. Resting blood flow in denervated small intestine usually ranged from 40-60 ml/(min. x 100 g) and flow could be experimentally increased to approx. 275 ml at a pressure head of 100 mm Hg. Blood flow covaried with the capillary filtration coefficient when a graded vasodilatation was induced; it was approx. 0.10-0.15 ml/(min. x 100 g) at rest and approx. 0.3-0.5 ml during max. vasodilatation. Max. blood flow of the mucosa was calculated to amount to 500 ml/(min. x 100 g) and the max. capillary filtration coefficient to approx. 1.0 ml/(min. x mm Hg x 100 g). Filtration gradually decreased and sometimes ceased within 10-15 min. when prolonged elevation of the mean capillary pressure was induced from the venous side. Prolonged stimulation of the intestinal vasoconstrictor fibers induced a specific circulatory pattern called "autoregulatory escape"; it was characterized by an initially pronounced constriction of the vascular bed followed by an escape of resistance vessels from nervous influence, usually within 1-2 min., while the perfused capillary exchange area remained reduced and the capacitance vessels maintained their constriction. When the steady state was reached during stimulation of constrictor fibers, the mean capillary pressure was normalized and usually maintained at the prestimulatory level; the pre-postcapillary resistance ratio, which increased during the initial phase of vasoconstriction, was also restored to the prestimulatory level. During the initial 1-2 min. of the poststimulatory period, the entire vascular bed dilated to a degree greater than that before stimulation. These characteristic changes in pattern of flow induced by sympathetic activity were not qualitatively different when blood flow was kept constant. The flow pattern was also mimicked when the sympathetic transmitter agent, norepinephrine, was infused intra-arterially during either constant pressure or constant flow. The characteristic changes were not induced by all vasoconstrictor agents; i.e., vasopressin, caused a sustained constriction of the resistance vessels, which was not followed by reactive hyperemia. The autoregulatory escape phenomenon also occurred when the sympathetic system was activated by stimulating the hypothalamic defense area; autoregulatory escape may be considered as a redistribution of blood flow, to some degree, from mucosa to submucosa. The regional increase in blood flow during the steady state phase of vasoconstrictor fiber stimulation was not due to the opening of true arteriovenous shunts. If preferential channels or other low resistance vessels are included in the response pattern, they must allow for diffusion exchange of solutes; therefore they cannot be regarded as true shunts. The discrepancy between blood flow and the perfused capillary surface area during constrictor fiber stimulation is apparently due to uneven perfusion, i.e., "physiological shunting".

5630 EFFECTS OF BRADYKININ, KALLIDIN, SEROTONIN AND HISTAMINE ON PANCREATIC BLOOD FLOW. (Fr.) Papp, M. (Inst. Exp. Res., Acad. Sci., Budapest, Hungary), G. B. Makara and B. Varga. Arch. Int. Pharmacodyn. 165(1): 31-36, 1967.

Low doses of bradykinin (0.1-0.6 μg/kg), kallidin (0.3 μg/kg) or serotonin (3.0 μg/kg), inj. into 1 of the pancreatic arteries, caused a sharp increase in pancreatic blood flow in dogs, probably as a result of local vasodilation. Serotonin induced a biphasic blood flow curve (a brief depression, followed by an increase to almost 200% and a slow decline), while the other 2 agents induced a briefer and sharper increase. Under these conditions arterial and portal venous pressure remained unchanged. In dogs treated with higher doses of bradykinin (0.5 or 1.0 μg/kg), kallidin (0.5 or 1.0 μg/kg) or histamine (5 or 10 μg/kg) by inj. into the thoracic aorta, a similar response was noted; serotonin (5 or 10 μg/kg) had no effect under these conditions.

5631 THE DISTRIBUTION OF SEROTONIN (5-HYDROXYTRYPTAMINE) IN THE GASTROINTESTINAL MUCOSA OF THE RAT: A COMPREHENSIVE STUDY. (E.) Thompson, J. H. (U. California Sch. Med., Los Angeles). Irish J. Med. Sci. (490):411-422, 1966.

Normal levels of gastrointestinal mucosal serotonin were determined in rats (Sprague-Dawley; Berkeley Pacific and Charles River strains) with respect to intestinal level and sex. Mucosal and comparative muscle samples were obtained from distal esophagus, stomach fundus, body and pylorus, upper and lower duodenum, mid-jejunum, terminal ileum, appendix (cecal tip), cecum, ascending, transverse and descending colon, and proximal rectum. Serotonin was assayed by extraction from total homogenates into n-butanol. In Berkeley Pacific rats, the highest mean serotonin levels were obtained in the pylorus (15.03±3.44 μg/g in 16 male and 20.57±3.21 μg/g for 11 female rats) and appendicular mucosa (14.52±4.14 μg/g in 13 male and 20.80±5.70 μg/g in 9 female rats). Male and female values for these 2 areas were significantly different for pyloric and appendicular values, resp. In the Charles River strain, no significant sex difference was observed in serotonin values, with the esophageal level reported low and varied (1.12±1.36 μg/g in 18 male rats, 2.21±1.80 μg/g in 16 female rats which probably reflected the varying density of argentaffin cells. In this strain also, mucosal serotonin levels were in the range of 0-3.7 μg/g and 0.4-2 μg/g for male and female rats, resp., and compared favorably with Berkeley Pacific rats with the pyloric and appendicular levels showing significant variance (differences in appendicular levels in male rats, pyloric and appendicular levels in female rats corresponded to probability values of $p < 0.001$, $p < 0.01$ and $p < 0.001$, resp.). No correlation between serotonin levels and rat wt. was observed. No measurable levels of serotonin were obtained from the muscle samples, indicating that removal of mucosa by scraping leaves negligible quantities of serotonin in subjacent muscle.

5632 IMPROVED ISOLATION OF ANAEROBIC BACTERIA FROM THE MOUSE CECUM BY MAINTAINING CONTINUOUS STRICT ANAEROBIOSIS. (E.) Spears, R. W. (Jefferson Med. Coll., Philadelphia, Pa.) and R. Freter. Proc. Soc. Exp. Biol. Med. 124(3):903-909, 1967.

Two technics for anaerobic culture were compared for their efficiency in isolating anaerobic bacteria from the mouse cecum. A conventional method, using a broth diluent and blood agar plates incubated in anaerobic jars, recovered only 1.1-5.8% of the total number of bacteria present. In contrast, 19.7-33.7% of the total bacterial count was recovered when the specimen was processed by the Hungate technic; the latter entailed anaerobic collection, dilution in reduced fluid under CO_2 and culture in roll tubes. Many bacteria isolated in this manner did not grow at all on blood agar plates incubated in anaerobic jars. The data presented suggest tha the predominant, strictly anaerobic bacteria of the cecal flora were sensitive to even transien contact with atmospheric O_2.

5633 THE DISTRIBUTION OF Cl. perfringens I THE INTESTINAL CONTENTS OF HEALTHY PERSONS. (Rus.) Sidorenko, G. I. (Pirogov 2nd Med. Inst., Moscow) and E. B. Borovik. Gig. Sanit. 31(10):29-33, 1966.

Feces samples collected from 1274 healthy individuals of various ages were examined for the presence of Clostridium perfringens. The incidence of positive isolations increased with increasing age, being 6.2 and 78.6% in samples collected from newborns and individuals older than 61, resp. A similar relationship was found between the conc. of Cl. perfringens in positive samples and the age of individuals. Of the 912 strains isolated 475 were nontoxic for white mice, whereas 437 were slightly toxic strains of type A of which 185 strains (20.4%) had a toxicity of 2-30 MLD per ml. Strains having spores resistant to heating were not isolated from feces of newborns, but they occurred frequently in samples collected from other groups. It was shown that Cl. perfringens infecting the intestinal tract of newborns may come from contaminated skin (hands, breast) or dust. Working conditions may also affect the incidence of Cl. perfringens in the intestinal tract of adults. The percentage of positive isolations from feces samples collected from personnel of subway stations was higher (98%) than that of samples taken from personnel working on the ground in a factory illuminated with artificial light (68%).

5634 POSTNATAL CHANGES IN PHOSPHATASE AND NONSPECIFIC ESTERASE ACTIVITY IN THE LARGE INTESTINE OF THE RAT. (E.) Masnerova, M. (Charles U., Prague, Czechoslovakia), O. Koldovsky and K. Kubat. Experientia 22(8):518-519, 1966.

Rats aged 1,3,7,10,15 and 20 days and adult animals were examined histochemically. Each age group contained 5 rats; sexes were about equal. Rats were decapitated 3 hr. after deprivation of food. Excisions of the cecum and the middle part of the oral and aboral half of the large intestine were fixed in Baker's formol-calcium at 4°C for 24 hr. and alkaline and acid phosphatases were determined in paraffi sections together with nonspecific and α-esterase In general, the alkaline phosphatase could be demonstrated in the brush border, apical and supranuclear Golgi zone of enterocytes, in the endothelium of some small vessels and capillaries in eosinophils, neutrophils, some macrophages and reticular cells of lymphadenoid tissue. The acid phosphatase is located in the same regions with the exception of the endothelium. Nonspecific-esterase is positive in the form of fine granules in the apical parts of the enterocytes in the Golgi zone; less fine granules to an intense diffuse reaction mark the basal parts of the enterocytes in the gland crypts. Eosinophils, neutrophils, macrophages, fibrocytes and probably some mast cells are also positive. A slightly positive nonspecific-esterase reaction was also found in smooth muscle cells of both muscular layers and the myenteric plexus. α-Esterase shows a less pronounced reaction in the same locations but cannot be demonstrated in the mast cells. The strength of these enzymes varies in different regions of the large intestine and from animal to animal. The activities of the 2 esterases are found in the cells on the first day and activity increases from the 20th day. Activity is highest in the adult. Enterocytes of the aboral part of the large intestine are also positive in contrast to the phosphatases.

5635 METABOLISM OF HISTAMINE-^{14}C IN NORMAL GUINEA PIGS OR AFTER PROLONGED HISTAMINE TREATMENT.

(Fr.) Andrzejewski, S. W. (Fac. Pharm., Paris, France) and Y. Cohen. C. R. Soc. Biol. (Paris) 161(10):1810-1814, 1966.

In guinea pigs treated with glucose soln. (1 ml/kg/day for 8-10 wk.), followed by a single inj. of ^{14}C-histamine (120 μg = 20 μc/kg i.v.), total radioactivity in the liver, ileum and stomach 15 min. later was 151.31, 74.53 and 63.54 nc/g tissue, resp. In the liver and ileum, most of this radioactivity was in the form of acid metabolites (148.24 and 66.13 nc/g, resp.), with trace quantities as unchanged histamine or methylhistamine. In the stomach, a larger proportion of the dose was found in the latter 2 forms (av. 13.68 and 27.75 nc/g, resp.). In guinea pigs treated for 8-10 wk. with unlabeled histamine (doses not stated), there was no significant change in label distribution in the liver, ileum or stomach, although a significant increase in acid metabolites at the expense of methylhistamine was noted in the kidneys and plasma.

5636 NITROGEN MUSTARD HYPERAMYLASEMIA AND INTESTINAL LESIONS.

(E.) Hiatt, N. (Cedars-Sinai Med. Ctr., Los Angeles, Calif.), N. E. Warner, G. Furman and M. Merchey. Surgery 61(4):596-601, 1967.

Mongrel dogs (40) were divided into 3 groups. In Group 1, 24 intact dogs were given an i.v. inj. of nitrogen mustard (1.5 mg/kg); 18 were then maintained (on nitrogen mustard) p.o., and 6 parenterally. In Group 2, 12 pancreatectomized dogs were given nitrogen mustard i.v., 6 immediately after the operation and 6 from 2 days-2 mo. after the operation; 6 were maintained p.o., and 6 parenterally. In Group 3, 4 dogs with well-healed Thiry-Vella fistulas of a 15-cm segment of the jejunum were given an i.v. inj. of nitrogen mustard and were subsequently maintained p.o. With the LD_{80} dose of nitrogen mustard, most of the dogs had diarrhea and anorexia within 2 days, and all animals lived at least 3 days; in 8 dogs the experiment was terminated on day 3. Of the remaining 32 dogs, 6 (19%) survived 10 days or longer. None of the others survived the fifth day, and nonsurvivors included all of the pancreatectomized dogs. In 14 dogs of Group 1, there was a sharp rise in the level of serum amylase on the second or third day, with a rapid return to the preinj. level in survivors; there was no apparent relation between the type of postinj. maintenance and the amylase response to nitrogen mustard. None of the dogs in Group 2 showed a significant change in the level of serum amylase after i.v. inj. of nitrogen mustard. In 3 animals in Group 3, there was a significant rise of serum amylase on the third day. Microscopically, the pancreas appeared to be normal in all of the intact dogs and in those with Thiry-Vella fistulas. In intact dogs, small intestine and lymph nodes showed typical changes associated with nitrogen mustard inj.; in pancreatectomized dogs, intestinal tract and mesenteric node lesions were less severe than those in intact dogs. The mustard lesions in dogs with Thiry-Vella fistulas were less severe than those of the small intestine in continuity of the same animal. The results of this study suggest that the small intestinal content, particularly the pancreatic juice, plays an important role in the development of nitrogen mustard lesions of the intestine.

5637 COLORIMETRIC METHOD OF MEASURING ELASTOLYTIC ACTIVITY IN EXTRACTS OF WHOLE PANCREATIC TISSUE.

(E.) Geokas, M. C. (U. Southern California Sch. Med., Los Angeles), S. Eisenstein, R. D. McKenna and I. T. Beck. J. Lab. Clin. Med. 69(3):530-536, 1967.

A colorimetric assay for elastase activity is reported; it is based on solubilization of an elastin-orcein substrate. The method has been adapted for quantitative determinations of free elastase and proelastase in whole extracts of normal and necrotic pancreatic tissue. An elastase unit was defined as that amount of enzyme which will render soluble 1 mg elastin-orcein substrate in 30 min. (between 10 and 40 min. reaction times) at 37°C in Tris buffer. A restricted set of conditions was formulated, including use of the 10-40 min. assay and a 5% dilution of whole pancreatic extract (containing both elastase components) on finely ground alkali-treated elastin in Tris buffer. Whereas linear elastolysis time curves were obtained when up to 64% of a 25 mg elastin-orcein substrate was rendered soluble, color interference and the slow initial phase of the reaction were nullified by use of the 30-min. assay. This method facilitates quantitative determinations of elastase and its zymogen in whole pancreatic extracts, and it is therefore suitable for studies of elastase activity in pancreatitis.

5638 REUTILIZATION OF DNA BREAKDOWN PRODUCTS FROM LYMPHOCYTES IN LUMEN OF INTESTINE. (E.) Kotani, M. (Kyoto U., Japan), A. Yamashita, F. Rai, K. Seiki and I. Horii. *Blood* 29(4): 616-627, 1967.

The migration of a large number of lymphocytes (211.8 x 10^6/day) into the intestinal canal of young male Wistar rats (100 g body wt.) was observed. In the intestinal lumen, approx. 80.2% of the lymphocytes were small, 15.9% were medium-sized and 3.9% were large. No recycling of the instilled cells into the intestine was noted. Lymphocytes labeled with ^{3}H-thymidine, obtained both from the thymus and mesenteric lymph nodes of donor rats, were washed and inj. into the intestine of recipient rats. ^{3}H-activity of the blood and thoracic duct lymph plasma after admin. of labeled lymphocytes revealed that DNA breakdown products from intestinal lymphocytes were absorbed and transferred through both the portal vein and the thoracic duct. Autoradiography showed that the activity was actually incorporated into the DNA of proliferating cells of the recipient.

5639 THE INTESTINAL RESPONSE TO HIGH BULK FEEDING IN THE RAT. (E.) Dowling, R. H. (Postgrad. Med. Sch., London), E. O. Riecken, J. W. Lawa and C. C. Booth. *Clin. Sci.* 32(1):1-9, 1967.

Rats were fed diets containing 66% (1:2 Group--diet containing 1 part by wt. of standard diet and 2 parts of powdered kaolin) and 80% (1:4 Group--diet containing 1 part of standard diet and 4 parts of powdered kaolin) by wt. of powdered kaolin for 9 mo. in order to assess the effect of increased dietary bulk on the intestinal tract. In addition, the functional response of the small intestine to this regimen was determined by measuring glucose transport using the everted sac technic. The anatomy of the intestine was studied radiologically in life and subsequently at autopsy. Rats whose diet was diluted with kaolin grew less well than controls, in spite of a marked increase in the wt. of the diet consumed; there was a corresponding increase in stool wt. as a result of the excretion of unabsorbed kaolin. There was no difference in the wt. of the stomach from the 3 dietary groups. Mean wt. of the small intestine of controls was 5.04 g (range 2.81-7.34) and there was no significant difference in small intestinal wt. in the bulk-fed animals. There was a marked increase in wt. of the cecum and colon in both groups of bulk-fed rats; whereas the mean colon wt. in the controls was 2.81 g (range 2.0-3.45 g), it was 3.79 g (range 3.05-4.29 g) in rats given the 1:2 diet and 4.09 g (range 2.85-6.09 g) in the 1:4 diet grou This increase was predominantly due to an increase in thickness of the muscle coat; this increase had developed within 3 wk. in rats fed either the 1:2 or 1:4 diet. Ba studies of the gastrointestinal tract in life showed no dilatation or hypertrophy of the small intestine but there was radiological dilatation of the cecum in bulk-fed rats and the wt. of the large intestine was significantly greater than in controls. After bulk feeding, the jejunum showed a marked increase in absorptive capacity of glucose and water. The mean glucose transport by control rats was 2.52 mg/100 mg dried intestinal tissue, whereas it was 4.81 mg by the 1:2 group and 9.96 mg by the 1:4 group. The difference in glucose transport between both bulk-fed groups was statistically significant, and that between controls and 1:4 kaolin-fed rats was highly significant. The vol. of net serosal fluid transfer for controls was 0.10 ml/100 mg dry wt. intestine, compared with 0.25 ml in the 1:2 group and 0.63 ml by the 1:4 group The histochemical enzyme pattern of small intestinal mucosa in bulk-fed rats showed an increase in the activity of leucine aminopeptida and to a lesser degree, an increase in glutamate and alcohol dehydrogenases when compared with the mucosa from control rats.

5640 COMPARISON BY RADIOGRAPHY AND MICRODENSITOMETRY OF EVACUATION OF THE GALLBLADDER IN A TELEOST (*Cyprinus carpio* L.) AND IN MAN. (Fr.) Toye-Lazarin, P. (Hotel-Dieu, Toulouse, France), G. Broussy and C. Laporte. *Rev. Canad. Biol.* 26(1):17-21, 1967.

5641 MODIFICATIONS OF THE EXOCRINE PANCREAS OF THE HEDGEHOG (ERINACEUS EUROPAEUS) DURING HIBERNATION. (It.) Bani Sacchi, T. (U. Florence, Italy). *Boll. Soc. Ital. Biol. Sper.* 42(22):1566-1568, 1966.

5642 MODIFICATIONS IN THE EXOCRINE PANCREAS OF THE ALBINO RAT DURING PROFOUND GENERAL HYPOTHERMIA. (It.) Bani Sacchi, T. (U. Florence, Italy) and A. Bolletti. *Boll. Soc. Ital. Biol. Sper.* 42(22):1565-1566, 1966.

5643 EFFECT OF THYROID EXTRACT AND PROPYLTHIOURAÇIL ON SALIVARY GLAND OF ALBINO RAT. (It.) Modica, R. (U. Turin, Italy) and F. Mongini. *Minerva Stomat.* 16(1):21-23, 1967.

644 UPTAKE AND SCANNING OF THE SALIVARY GLANDS IN MAN USING PERTECHNETATE-
9mTc. (E.) Harden, R. M. (Gardiner Inst.,
lasgow, Scotland), T. E. Hilditch, I. Kennedy,

lin. Sci. 32(1):49-55, 1967.

645 DEUTERIUM OXIDE EXCHANGE IN ISOLATED GUINEA-PIG TAENIA COLI. (E.) Elford, B. C. (Nat. Inst. Med. Res., London). J. Physiol. (London) 188(2):29P-30P, 1967.

5646 INORGANIC IONS IN CECAL CONTENT OF GNOTOBIOTIC RATS. (E.) Asano, T. (U. Notre Dame, Ind.). Proc. Soc. Exp. Biol. Med. 124(2):424-430, 1967.

5647 THE COMMON BILE DUCT IN MAN: ITS DIAMETER AND CIRCUMFERENCE. (E.) Mahour, G. H. (Mayo Clin., Rochester, Minn.), D. G. Wakim and D. O. Ferris. Ann. Surg. 165(3): 415-419, 1967.

Autopsy studies were made on 100 selected subjects whose ages ranged from 15-102 yr. and who had intact biliary tracts. Outer diameters and inner circumferences of the ducts av. 7.39 and 14.99 mm, resp. Correlations between caliber variations of the duct and age of the subject demonstrated a definite increase of both outer diameter and inner circumference with age in both men and women. No relationship between caliber variations and body length or body wt. was observed.

5648 ELECTRON MICROSCOPIC ASPECTS OF HEPATIC INTRACELLULAR COMMUNICATIONS. (Rum.) Pavel, I. (Dr. J. Cantacuzino Hosp., Bucharest, Rumania), S. Campeanu, H. Bonaparte, A. Petrovici and M. Stoian. Stud. Cercet. Med. Intern. 7(5):457-460, 1966.

From the electron microscope findings illustrated, it is concluded that there are intracellular communications of sinusoid aspect connecting Disse's space with the biliary canaliculi, which, at certain points, exhibit zones of coalescence (so-called impermeable junctions) intermediate or adherent (desmosomes), but do not interrupt this connection. These intracellular spaces may, on occasion, become visible routes of communication, and the fact that they have been declared impermeable by some authors is due only to their having been observed in periods of functional rest. That they are more conspicuous in certain pathologic states does not testify to their pathologic significance, but merely reflects certain pre-existing and current morphologic aspects which remain to be defined.

5649 VARIATION OF THE ARTERIES SUPPLYING THE LIVER IN MAN. (Pol.) Nowak, M. (Inst. Norm. Anat., Warsaw). Folia Morph. (Warsz.) 25(3):277-284, 1966.

The variability of hepatic arterial vascularization was studied on 110 cadavers (87 male, 23 female; age varied from 53-74 yr.). The vessels emanating from the branch of the splanchnic trunk and upper mesenteric arteries were considered. Six forms of hepatic vascularizations were recognized, depending on the number and the starting site of the arterial branches reaching the liver. In the first form (56.4% of the cases), the liver was supplied by the hepatic artery alone. In the second form (1.8%), the hepatic artery was missing; the liver received right and left hepatic arteries from the gastroduodenal artery. In the third form (28.2%), the liver was vascularized by the hepatic artery and left supplementary hepatic artery. In the fourth form (9.1%), the liver was supplied by the hepatic artery and the right supplementary hepatic artery. In fifth form (3.6%), the live was supplied by the hepatic artery and left and right supplementary hepatic artery. In the sixth form (0.9%), the liver was vascularized b the hepatic artery, 2 left supplementary hepati arteries and 1 right supplementary hepatic artery.

5650 AN ELECTRON MICROSCOPIC STUDY OF THE EPITHELIUM OF NORMAL HUMAN SIGMOID COLONIC MUCOSA. (E.) Pittman, F. E. (Queen Elizabeth Hosp., Birmingham, England) and J. C. Pittman. Gut 7(6):644-661, 1966.

Early undifferentiated cells and goblet cells were observed at the base of the crypts in the 17 subjects studied. Examination of goblet cells showed the presence of cytoplasmic alpha-cytomembranes; granules, mitochondria and vesicles in the cytoplasm of more matured cells mucin droplets arising from 'stacked' membranes of the supranuclear Golgi apparatus; a spherica unit structure of mucin droplets at high power; interdigitation of lateral membranes; a basilar membrane composed of electron dense spherical units overlying a layer of filamentous material perinuclear cisterna perhaps permitting free exchange of cytoplasm and nucleoplasm. Inspection of chief cells showed the limiting membrane of the microvilli to be composed of spherical units and filamentous material. Filaments were seen to extend from the entire microvillar surface with round structures observable in the microvillar border, probably resulting from microvillar degeneration. A network of filaments (approx. 0.25 μ) was seen beneath the basement membrane of chief cells. Argentaffin cells were observed occasionally in the base of the crypts and were characterized by cytoplasmic electron dense bodies.

5656 RELATIONSHIPS BETWEEN INTESTINAL ABSORPTION OF ACTIVELY TRANSPORTED OR DIFFUSING SUBSTANCES AND CONCENTRATION OR TRANSPORT OF Na$^+$. (Ger.) Lauterbach, F. (Madaus Inst., Cologne-Merheim, Germany). Biochim. Biophys. Acta 135(2):256-272, 1967.

The influence of Na conc. and Na transport on enteric absorption of either actively transported or diffusing substances was studied by perfusion of guinea pig and rat small intestine in vitro, according to the method of Fisher and Parsons. Na conc. of the perfusing soln. was varied by isotonic exchange of NaCl with mannitol. Two relationships were found which correlated Na and glucose absorption: 1) there was a strong linear correlation between Na absorption and glucose if Na conc. was held constant; and 2) the regression coefficient decreased with increasing Na conc. of the perfusing soln.; therefore, the ratio of the absorbed amounts:glucose/Na decreased with increased supply of Na. The same relationships were true for the absorption of K and Ca. A proportionate rise in Na absorption occurred with increasing levels of Na in the perfusing fluid; simultaneously, the mean absorption of K, Ca and glucose increased and showed saturation kinetics, although their conc. was kept constant. Cortisol absorption by the perfused small intestine and urea penetration across the wall of everted intestinal sacs were both independent of the Na conc. of the perfusion and incubation media. These findings suggest that the actively transported substances, K, Ca and glucose, are each absorbed principally by the same mechanism, which functions through common transport sites. The proportional quantity of Na and other substances transported may be determined by the number of these sites, while the ratio between the mass of substance and the mass of Na transported can be determined by the particular functional character of these sites. Theoretical difficulties which arise from such a common transport site hypothesis in which Na and, e.g., glucose are assumed to be complexed and carried by the same active carrier are discussed.

5657 EFFECT OF DIETARY PROTEIN DEFICIENCY ON INTESTINAL ABSORPTION AND TISSUE DISTRIBUTION OF ABSORBED ^{59}Fe IN MALE RATS. EFFECT OF ERYTHROPOIETIN INJECTIONS. (Fr.) Aschkenasy, A. (Hemat. & Endocrin. Lab., Montrouge, Seine, France). Rev. Franc. Etud. Clin. Biol. 11(10):1010-1022, 1966.

In rats fed a protein-deficient diet for 7 days, ^{59}Fe absorption (0.2-0.4 mc p.o.) was nearly normal (mean 24.6%), but RBC utilization of absorbed iron was almost completely suppressed (mean 0.10%). After 7 wk. of nitrogen starvation, iron absorption fell to 10.2%, but RBC utilization of absorbed iron increased (mean 1.87%; normal 7.32%). Treatment with erythropoietin-rich plasma at the beginning of nitrogen starvation enhanced utilization of absorbed iron (2.47%) without increasing iron absorption. In rats fed a balanced diet for 10 days after 7 wk. of nitrogen starvation, iron absorption and RBC incorporation of absorbed iron markedly increased. In rats on normal and low-protein diets, ^{59}Fe absorption was much higher after i.v. than p.o. admin., but after 1 wk. of protein deprivation i.v. ^{59}Fe accumulate in the liver to a much greater extent than absorbed iron. Retention of label in the intestinal wall was markedly increased by protein deficiency.

5658 COMPARATIVE EFFECTS OF CASEIN AND DIFFERENT AMINO ACID MIXTURES ON INTESTINAL ABSORPTION OF ^{59}Fe AND ERYTHROPOIETI UTILIZATION OF ABSORBED RADIOIRON IN PROTEIN-DEFICIENT RATS. (Fr.) Aschkenasy, A. (Lab. Hematol. Endocr., C.N.R.S.-E.R. S.I., Montrouge France). C. R. Soc. Biol. (Paris) 160(7): 1383-1386, 1966.

Intestinal ^{59}Fe absorption in rats fed an 18% casein diet was 28%; after prolonged admin. of a protein-free diet it fell to 14%. When casei was restored, absorption rose to 27%; admin. of a complete amino acid mixture was even more effective (37.3%). Reticulocyte isotope uptake with the complete amino acid mixture was also stimulated, but to a lesser extent. Omission of a single essential amino acid from the mixture prohibited this stimulation of ^{59}Fe absorption during the recovery period; a deficiency of tryptophan, histidine or valine was even more injurious than a nitrogen-free diet. Erythropoietic utilization of absorbed iron was also controlled by dietary amino acids particularly histidine.

5659 THE MECHANISM OF DESQUAMATION OF CELLS FROM THE INTESTINAL VILLI (AN ELECTRON MICROSCOPE STUDY). (Ger.) David, H. (Humboldt U., Berlin). Virchow. Arch. Path. Anat. 342(1):19-25, 1967.

The epithelium of the small intestine in man in the normal state and during chronic enteritis, and also the normal and ischemic small intestinal epithelium of the rabbit were studied under the electron microscope to determine if relatively large particles, up to 100 μ, such as starch grains, gain entry to the lymphatic system and the blood in the regions of the epithelium where cells have undergone necrosis and desquamation. Under normal conditions in both man and rabbit desquamation takes place after the cellular components degenerate, with shrinkage and pyknosis of the cell; this occurs with no break in the continuity of the epithelia covering. The adjacent healthy epithelial cells press the degenerating cell out of the complex from below, simultaneously closing the area occupied by the desquamated cell. Under pathologic conditions the cells leave the epithelial layer before the space occupied by them is sealed by the adjacent cells; these breaks in the epithelium allow the passage of bacteria and particles of various sizes. Particles must pass through the barrier of the healthy epithelium by phagocytosis or possibly by being pressed into goblet cells.

5660 TISSUE CULTURE OF CALF INTESTINE. STUDY OF CELLULAR DIFFERENTIATION AND DISACCHARIDASE ACTIVITIES. (Fr.) Capdeville, Y. (Child. Hosp., Paris), J. Frézal, J. Jos, J. Rey and M. Lamy. *C. R. Acad. Sci. (Paris)* 264(3)(Ser. D):519-521, 1967.

Tissue homogenates from jejunal villi of a calf were explanted *in vitro*. The explants began to grow after about 10 days of cultivation; some died, but 1 strain became adapted to the *in vitro* conditions and had been cultivated about 4 mo. at the time of report. Fibroblasts and plaques of epithelial cells were seen throughout this time; intra- and extracellular mucopolysaccharides were found in the first 2 mo. of cultivation at least (no studies were made thereafter). The karyotype (58 acrocentrics + 2 submetacentrics) remained unchanged. Saccharase and isomaltase were absent at all times (in the original intestinal homogenate and after up to 14 passages *in vitro*); α-glucosidase activity remained unchanged, lactase fell to trace levels and maltase activity increased during *in vitro* cultivation.

5661 RESECTION OF THE SMALL INTESTINE IN RATS. I. NUTRITIONAL STATUS AND ADAPTATION OF FAT AND PROTEIN ABSORPTION. (E.) Nygaard, K. (Rikshospitalet, Oslo, Norway). *Acta Chir. Scand.* 132(6):731-742, 1966.

Resection of 25, 50, and 75% of the proximal and of the distal small intestine with end-to-end anastomosis was performed in rats. Hemoglobin levels and body wt. was determined before and various periods after operation. Fat and nitrogen balance studies were done. Distal resections affected body wt. more than proximal resections. Proximal resections up to 75% were without effect on hemoglobin levels; distal resections caused a significant reduction. Fat and nitrogen excretion were near normal 3 mo. after proximal resections of up to 75%. After distal resections excretion rose proportionally with the amount of intestine removed. Balance studies at intervals after proximal resections showed moderate malabsorption 6-12 days postoperatively and normal levels within a few mo. Following distal resections fat and nitrogen loss was large immediately following operation and had only partially adapted in 9 mo. Adaptation was slower for protein than for fat for both conditions. It is concluded that adaptation takes place rapidly after proximal resections of the small intestine, whereas adaptation is slower and incomplete after distal resections. The findings were taken to indicate that fat and protein are absorbed throughout the entire small intestine of the rat.

5662 RESECTION OF THE SMALL INTESTINE IN RATS. II. ABSORPTION OF VITAMIN B_{12}, WITH SPECIAL REGARD TO ADAPTATION OF ABSORPTION. (E.) Nygaard, K. (Rikshospitalet, Oslo, Norway). *Acta Chir. Scand.* 132(6):743-750, 1966.

Resections of the proximal 50 and 75% and of the distal 25, 50 and 75% of the small intestine with end-to-end anastomosis were carried out in rats. Absorption of ^{58}Co-labeled vitamin B_{12} was measured at various intervals after the operation. Some adaptation to the malabsorption of vitamin B_{12} was evidenced immediately following operation. The adaptation was more pronounced after proximal than after distal resections. After proximal resections rapid adaptation occurred and absorption was normal within 10 days following 50% resections; after 75% proximal resections the absorption was only partially normalized within 10 days and approached normal levels at 11 mo. After 50% distal resections adaptation was slow but approached normal levels by 6 mo. Following 75% distal resections normal levels were not reached 11 mo. after operation, although some adaptation had occurred. The patterns observed were considered similar to those reported for fat and protein absorption after resection. It is concluded that the proximal quarter of the intestine and the duodenum play a limited role in the absorption of B_{12}. The middle half of the intestine was considered the most likely place of absorption for B_{12} in the rat.

5663 EFFECT OF INTRINSIC FACTOR ON ABSORPTION OF VITAMIN B_{12} FROM SMALL INTESTINE. (E.) McColl, I. (Guy's Hosp., London S.E. 1), D. Andrews, J. C. Gazet, J. L. Raven and S. Streek. *Lancet* 1(7489):544-545, 1967.

Segments of jejunum and distal ileum were washed out during operation and isolated by clamps using previously reported methods. Soln. of normal saline containing radioactive B_{12} were inj. into 4 segments of equal area, two of jejunum and two of ileum. Hog intrinsic factor was added to one jejunum and one ileum segment. In one patient gastric juice was added instead of intrinsic factor. After 15 min. the soln. was aspirated from the segments, vol. noted and radioactivity measured in a scintillation counter. Serum B_{12} was determined by microbiological technics. Intrinsic factor had no obvious effect on the percentage absorption of B_{12}. The lowest of 3 conc. of B_{12} soln. used was less than the serum conc. Varying conc. of intrinsic factor in two patients had no effect on absorption. Gastric juice was similar in activity to hog intrinsic factor. Liver uptake of B_{12} was not affected by intrinsic factor in the 2 patients studied. The addition of Ca gluconate to the soln. in one patient did not affect absorption. It is tentatively concluded that hog intrinsic factor does not enhance absorption of B_{12} under the conditions of the experiment. Intrinsic factor may have a protective role on B_{12} absorption rather than a direct action, and possibly may have no role at all in a normal man whose intestine is free of coliform organisms competing for B_{12}.

5664 STRUCTURAL AND FUNCTIONAL CHANGES FOLLOWING SMALL INTESTINAL RESECTION IN THE RAT. (E.) Dowling, R. H. (Postgrad. Med. Sch., London) and C. C. Booth. Clin. Sci. 32(1):139-149, 1967.

Extensive resection of the proximal or distal small intestine was performed on Wistar strain rats. The histology and gross anatomy of the residual small intestine was studied at various intervals of time after surgery, and glucose absorption was measured with an *in vivo* recirculation technic. Similar studies were performed after ileo-jejunal transposition without resection. Enhanced glucose absorption and mucosal hypertrophy were noted in the intestinal remnant after extensive small intestinal resection in the rat; these compensatory changes developed in as short a period as 2 wk. after resection and were max. at 1 mo. These responses occurred to a much greater degree in the ileal remnant after proximal resection than in the jejunum after distal resection. The increased load of nutrients derived from the intestinal lumen may possibly be the stimulus to the greater hypertrophy that occurred in the ileum, since after ileo-jejunal transposition without resection the juxtaposed ileum displayed marked hypertrophy and enhanced absorption of glucose.

5665 SALT AND WATER ABSORPTION FROM THE NORMAL HUMAN COLON: EFFECT OF 9-ALPHA-FLUOROHYDROCORTISONE ADMINISTRATION. (E.) Levitan, R. (Tufts U. Med. Sch., Boston, Mass.). J. Lab. Clin. Med. 69(4):558-564, 1967.

The entire colon of 31 healthy, unanesthetized, well-hydrated subjects (29 men, 2 women; 20-65 yr. old) was perfused at a rate of 10 ml/min. by means of a perorally introduced polyvinyl tube located in the cecum. The test soln. consisted of 0.85% NaCl containing a nonabsorbable marker, polyethylene glycol (in the conc. of 0.5%). The absorption and secretion of Na, K, HCO_3, Cl and water from and into the test soln. were measured after it had traversed the colon. Unidirectional fluxes of ^3H_2O, ^{24}Na, and ^{42}K from and into the colonic lumen were also determined in several experiments. Colonic absorption from the test soln. was as follows: water, 2.11±1.5 ml/min.; Na, 0.38±0.24 mEq/min., and Cl, 0.57±0.27 mEq/min.; at the same time, K, 0.03±0.03 mEq/min., and HCO_3, 0.15±0.07 mEq/min., were added to the test soln. Unidirectional fluxes of water, Na and K were as follows: 1) water flux out, 7.38±1.6 ml/min.; flux in, 5.6±1.6 ml/min.; 2) Na flux out, 0.51±0.26 mEq/min., flux in, 0.28±0.51 mEq/min.; and 3) K flux out, 0.020±0.009 mEq/min.; flux in, 0.051±0.02 mEq/min. There was a significant increase in net absorption of Na, Cl and H_2O from the test soln. in all experiments 24 hr. after i.v. admin. of 2 mg of 9-α-fluorohydrocortisone to 5 normal subjects who were in the recumbent position and on a daily intake of 9.0 g of salt. Mean net absorption of Na for the entire study group rose from 0.46 mEq/min., to 0.71 mEq/min.; Cl rose from 0.73 mEq/min. to 0.96 mEq/min. and H_2O from 2.7 ml/min. to 4.1 ml/min. Mean H_2O flux out of the lumen was 7.82 ml/min. before and 7.58 ml/min. 24 hr. after the admin. of 9-α-fluorohydrocortisone. The calculated mean water flux into the lumen changed from 5.08 ml/min. during control studies to 3.48 ml/min. 24 hr. after hormone admin.

5666 ACTIVE SODIUM TRANSPORT BY THE COLON OF *Bufo marinus*: STIMULATION BY ALDOSTERONE AND ANTIDIURETIC HORMONE. (E.) Cofré, G. (Univ. Clin. St. Pierre, Louvain, Belgium) and J. Crabbé. J. Physiol. (London) 188(2):177-190, 1967.

Isolated colon of *Bufo marinus* transports Na actively from the mucosal (lumen) to the serosal side; this transport is expressed quantitatively by the short-circuit current. Short-circuit current remained a fair expression of Na transport from mucosa to serosa when Na was diluted in Ringer soln. on the mucosal side of the preparation. The relationship between short-circuit current and dilution of Na of the luminal side was examined and found to be curvilinear; this suggested the intervention of a saturable step in the transport of Na from lumen to serosal surface of colon. The relationship between short-circuit current and the amount of Na drawn from the luminal side and recovered in the membrane (active Na transport pool) was almost linear; this indicated that the "pump" operated far from capacity. Therefore the observed saturation of Na transport, when conc. of Na on the mucosal side was increased, probably occurred at the mucosal border of the preparation. After treatment with aldosterone, the "active Na transport pool" and short-circuit current increased to the same degree; from this it was inferred that the hormone merely allowed Na easier access to the "pump" which would react in proportion. Consequently, no direct influence of aldosterone on the "pump" proper was postulated. After exposure of the colon to antidiuretic hormone, there were modest increases of short-circuit current and of osmotic water flow across the wall of the organ.

667 FURTHER STUDIES ON INTESTINAL ACTIVE TRANSPORT DURING SEMISTARVATION. (E.) Hindmarsh, J. T. (Roy. Infirm., Sheffield, England), D. Kilby, B. Ross and G. Wiseman. J. Physiol. (London) 188(2):207-218, 1967.

The influence of semistarvation (sufficient to produce a loss of 18-28% of initial body wt.) on the active transport of D-glucose and L-histidine by the guinea pig, golden hamster and rat was studied using sacs of everted small intestine (from upper jejunum to lower ileum). In rat and guinea pig, dietary restriction produced an increased active transport in all regions of the small intestine; in contrast, it caused no alteration in active transport in the hamster. Response in the rat was most impressive in the middle-to-lower ileum during uptake of D-glucose. While normal sacs from this region were unable to move glucose against its conc. gradient, sacs from semistarved rats did this quite well. Although there was a considerable loss (24-29%) of intestinal dry wt. in all 3 species when food intake was decreased, shortening of the small intestine was not detectable in hamster or guinea-pig, and it occurred only to a minor degree in the rat. Evidence is discussed that the enhanced active transport was not merely a reflection of the thinning of the intestinal wall, and that it occurred during complete as well as in partial starvation.

5668 ABSORPTION AND METABOLISM OF UNIFORMLY ^{14}C-LABELED PHYTOL AND PHYTANIC ACID BY THE INTESTINE OF THE RAT STUDIED WITH THORACIC DUCT CANNULATION. (E.) Baxter, J. H. (NHI, NIH, Bethesda, Md.), D. Steinberg, C. E. Mize and J. Avigan. Biochim. Biophys. Acta 137(2):277-290, 1967.

Absorption (approx. 70% thru intestinal lymphatics) of tracer doses of ^{14}C-labeled phytol (0.2 mg with 1-1.5 μc) from the rat intestine was 51% (39-73%) of recovered radioactivity (91%) after a 24-hr. period. ^{14}C-labeled phytol was admin. by gastric intubation in all 5 rats, and the radioactivity measured periodically from the lymph by way of a cannulated thoracic duct, expired $^{14}CO_2$, urine and body tissues (24 or 48 hr.). When the amount of phytol admin. was increased to 300 mg, a smaller fraction was absorbed but max. absorption attained levels of 65 mg. Both phytol and cetyl alcohol were absorbed more slowly and less completely than phytanic and palmitic acids (71% and 71% resp. for the former two compared to 85% and 95% resp. for the latter, employing 0.2 mg doses in all instances) as well as less exclusively thru the intestinal lymphatics.

5669 NON-SPECIFICITY OF THE DIVALENT CATION CAPABLE OF RESTORING NORMAL INTESTINAL PERMEABILITY AFTER CHELATION DEPLETION. (E.) Goldner, A. M. (Harvard Med. Sch., Boston, Mass.), M. M. Cassidy and C. S. Tidball. Proc. Soc. Exp. Biol. Med. 124(3):884-887, 1967.

The intestine of fasted male rats was divided into 3 segments. Control and experimental segments were randomized. All soln. placed in the segments were adjusted to pH 7.0 and 30 mOsm/liter. The absorption of phenol red was used as an index of passive aqueous permeability. $BeCl_2$, $MgCl_2$, $CaCl_2$, $SrCl_2$ and $BaCl_2$ were able to restore normal aqueous permeability of the mucosal epithelial membrane following chelation depletion by Na_2H_2-ethylenediamine tetracetic acid. Each alkaline earth metal was capable of permeability reinstatement at a minimal conc. These levels of replacement were in accord with the position of the elements in the periodic table. The relationship between minimal replacement conc. and charge density appeared to indicate that a physical property of these ions was involved in the restoration of permeability rather than a specific biochemical characteristic. The particular alkaline earth metal, or combination, physiologically responsible for regulation of permeability and cell adhesion in epithelial tissue cannot be specified with any degree of certainty.

5670 THE EFFECT OF DOSE ON D-XYLOSE EXCRETION. (E.) Clark, P. A. (Barnet Gen. Hosp., Herts., England) and W. A. Harland. Amer. J. Dig. Dis. 12(2):183-188, 1967.

D-Xylose excretion tests were performed on rats following an overnight fast. Doses ranging from 0.02 to 512 mg were admin. both p.o. and i.p. dissolved in 1.6 ml of tap water. Urine was collected in glacial acetic acid for 8 hr. following dosing and the xylose content estimated. The urinary excretion of xylose following i.p. doses was remarkably constant over a wide dose range; the urinary excretion plotted against dose yielded a linear function. Following oral admin. the excretion pattern differed from the i.p. pattern. A mean excretion of 44% was observed with doses less than 24 mg but beyond this point, with doses from 32 to 512 mg, 23% of the dose was excreted. The authors conclude that the efficiency of absorption is affected by conc. of xylose in the small intestine. The reciprocal of the oral dose plotted against the reciprocal of excreted xylose yielded a straight line indicating the existence of a rate-limiting step in absorption. These findings suggest that in the rat there is a limited mechanism for facilitating the absorption of xylose. The experiments do not distinguish between the possibilities of a limited active transport mechanism, against a conc. gradient, or some mechanism of facilitated diffusion.

5671 THE EFFECT OF DIETARY CALCIUM ON THE ABSORPTION AND RETENTION OF RADIOSTRONTIUM. (E.) Nordin, B. E. C. (Gen. Infirm., Leeds, England), D. A. Smith, J. Shimmins and C. Oxby. Clin. Sci. 32(1):39-48, 1967.

The subjects were 32 patients (11 men and 21 women) under investigation in a metabolic ward for disorders of Ca metabolism. All were receiving constant diets on which they were equilibrated for 5-6 days before feces and urine collections were begun. Radiostrontium (^{85}Sr) was admin. twice daily with food in a dose of approx. 0.25 μCi as the chloride. Radioactivity in plasma, urine and feces was determined in a well-type counter. Fecal radioactivity ranged from 31.8-100.5% of the daily admin. dose and was positively correlated to the Ca intake. Urinary radioactivity ranged from 0.5-34.5% of the daily admin. dose and was negatively related to the Ca intake. Owing to the opposite effect of dietary Ca on fecal and urinary activity, Ca supplementation did not have a significant effect upon ^{85}Sr retention. When Ca supplements were given, retention fell substantially in 7 patients, but remained unchanged or rose in the remainder. The stated implication of this work for protective measures against ingested radiostrontium is that dietary supplementation would not be a useful procedure.

5672 FINE STRUCTURAL LOCALIZATION OF LYSOSOMAL ENZYMES IN THE ABSORBING CELLS OF THE DUODENAL MUCOSA OF THE MOUSE. (E.) Hugon, J. (Ctr. Study Nucl. Energy, Mol, Belgium) and M. Borgers. J. Cell. Biol. 33(1)(Pt. 1): 212-218, 1967.

BALB/c adult male mice fasted for 18 hr. were sacrificed by ether anesthesia. The duodenum was fixed in 5% cacodylate-buffered glutaraldehyde for 2 hr. at 4°C then quenched in precooled isopentane and sectioned at 30 μ. The sections were incubated in appropriate media for: acid phosphatase activity, arylsulfatase activity, E-600-resistant esterase activity and alkaline phosphatase activity. Post-fixation was in 2% OsO$_4$, embedding in Epon. The sections were examined unstained or stained with uranyl acetate-lead nitrate in a Philips electron microscope. The localization of acid phosphatase activity was mainly in the dense bodies, abundant in the apical part of the duodenal absorbing cells. Arylsulfatase activity shown by a heavy precipitate of barium sulfate localized on one side of the dense bodies. Multivesicular bodies were seldom regularly stained but frequently contained one or two vesicles with the specific precipitate. E-600-resistant esterase activity was clearly localized, particularly on nearly all the dense bodies. Alkaline phosphatase activity was localized on the microvilli, the smooth reticulum profiles, the multivesicular bodies, the Golgi cisternae and nearly all the dense bodies. The latter had the same morphological aspect as those bodies that were positive for the preceding 3 lysosomal enzymes. The presence of 3 acid hydrolase activities in bodies showing a morphologic pattern identical with that of bodies containing alkaline phosphatase activity is forwarded as a new argument for the presence of alkaline phosphatase in the lysosomes of the absorbing cells of the duodenum.

5673 ELECTRON CYTOCHEMICAL EXAMINATION OF THE THIAMINE PYROPHOSPHATASE ACTIVITY IN THE INTESTINE OF THE RAT. (E.) Saito, T. (Kansai Med. Sch., Osaka, Japan) and K. Ogawa. Nippon Soshikigaku Kiroku (Arch. Histol. Jap.) 27(1-5):473-484, 1966.

The activity of thiamine pyrophosphatase in the normal rat intestine (jejunum, ileum, colon) was investigated. It was strongly positive in the Golgi complex (lamellated cisternae, vesicles and vacuoles) in both the absorptive cells and the goblet cells. Among colonic goblet cells, the Golgi complex of young maturing goblet cells revealed higher enzymatic activity than that of well-matured goblet cells containing numerous mucigen droplets. A probable participation of thiamine pyrophosphatase with the mechanism of cyclic secretion of goblet cells through the Golgi complex was postulated. Enzymatic activity was also observed in the plasma membranes covering microvilli, interspaces between lateral cell surfaces forming plications, the nuclear envelope, the rough-surfaced endoplasmic reticulum and, occasionally, lysosomes in the absorptive cells. Pinocytotic vesicles seen in the vascular endothelium and the smooth muscle cell and axon-Schwann interfaces also revealed positive enzymatic activity.

5674 IN VITRO STUDIES ON THE INTESTINAL TRANSPORT OF AMINO ACIDS AND A SUGAR IN HYPOTHYROID RATS. (E.) London, D. R. (St. Thomas' Hosp., London, S. E. 1) and S. Segal. Endocrinology 80(4):623-628, 1967.

The in vitro uptake of cycloleucine, histidine, valine and α-methyl-D-glucopyranoside into intestinal segments of hypothyroid rats was studied. Segments of jejunum were obtained from animals that had been made hypothyroid by thyroidectomy followed by admin. of 0.5 mC ^{131}I, as well as from control euthyroid animals. With each substance, and at all time points studied, there was an increased intracellular accumulation in the hypothyroid group. This effect was diminished by treating the animals with parenteral triiodothyronine (15 μg) for 4-5 days. When valine accumulation was studied in more detail, no difference was found in the efflux of amino acid from the segments in the hypothyroid and control animals. Michaelis-Menten studies revealed that intestine from hypothyroid rats had a higher transport velocity than either the control or treated hypothyroid group. Valine accumulation was not altered by thyroxine added to incubation flasks containing tissue from the hypothyroid rats. It is suggested that in hypothyroidism there may be an alteration of the transport carrier to give an increased rate of amino acid and sugar transport into the intestinal mucosal cell.

5696 BLOOD FLOW AND SECRETION IN THE STOMACH. (E.) Jacobson, E. D. (U. California, Los Angeles), K. G. Swan and M. I. Grossman. Gastroenterology 52(2)(Pt. 2):414-422, 1967.

A series of studies investigating the relationship between blood flow and gastric secretion were carried out in dogs prepared with vagally denervated Heidenhain pouches of the oxyntic gland area of the stomach. Gastric mucosal blood flow was measured by clearance of aminopyrine by the stomach (comparison of plasma and gastric juice levels). Total arterial inflow to the pouch was measured by chronically implanted electromagnetic flow meters. Infusion of progressively increasing doses of histamine (augmented by bethanechol) increased gastric secretion with increasing dose and was accompanied by correlative increases in gastric mucosal blood flow. A similar relationship was found following inj. of porcine gastrin extract, synthetic pentapeptide, insulin and 2-deoxy-D-glucose. Histamine-induced increases in secretion and mucosal blood flow were depressed in a parallel fashion by pitressin; similar effects were produced by atropine, epinephrine, secretin, and isoprenaline. With low doses of isoprenaline it was possible to increase mucosal blood flow with no effect on gastric secretion. In experiments with graded doses of histamine a 6-fold increase in secretory rate was accompanied by a 4-fold increase in mucosal blood flow with no change in pouch total arterial inflow. Similar data were gathered with extracted and synthetic gastrin. It is concluded that changes in secretory rate were accompanied by directionally corresponding alterations in mucosal blood flow but there is no apparent correlation between secretory changes and alterations in arterial inflow in a variety of situations. The relationship between secretion and blood flow appears to be one in which changing secretory activity induces a corresponding alteration in the local blood supply. In discussion somewhat similar data relying on clearance of ^{42}K to measure mucosal blood flow in anesthetized dogs with intact stomachs were cited showing no change in flow following inj. of secretin, and increased flow following inj. of epinephrine. The differences were not resolved.

5697 MAXIMAL HISTAMINE SECRETION TEST (KAY'S TEST). PROCEDURE AND RESULTS IN NORMAL SUBJECTS. (It.) De La Pierre, M. (U. Turin, Italy), S. Gabasio and G. Bruno. Minerva Med. 57(73):2933-2940, 1966.

Results obtained with the Kay test of maximal histamine secretion are reported in 84 normal subjects (49 men and 35 women; 41 under and 43 over 30 yr. old) and in 10 patients with various gastric diseases. The procedure is outlined and included the following modifications propose by the authors: inj. of antihistamine (mepyramine) 30 min. instead of 1 hr. after the beginni of the test; use of a mechanical aspirator of gastric juice during the first 5 min., followed by spontaneous flow for the next 5 min., followed by manual aspiration during the remaini 5 min. Both the vol. and HCl content of gastric secretion were the same before and after the inj. of Neoantergan. A good variability coefficient was observed in 9 subjects tested twice, with intervals varying from 1 wk. to 3 mo. betwe tests. The vol. of gastric secretion was greate in men than in women of the same age group, especially in younger subjects. Acid content was greater in subjects of both sexes under 30 yr. old; the difference was more evident at pH 7.

5698 GASTRIC SECRETION STIMULATED BY MEAT EXTRACT IN MAN. A TEST OF ANTRAL FUNCTION. (E.) Giles, G. R. (U. Leeds, England) and C. G. Clark. Scand. J. Gastroent. 1(3): 159-166, 1966.

Gastric secretion studies were performed in 14 normals and 40 chronic duodenal ulcer patients. Following an overnight fast secretions were gathered by nasogastric tube. After one hr. of basal collection, 100 ml of meat extract was introduced into the stomach, left for 15 min. and then aspirated. Secretions were gathered for an additional hr. Histamine-stimulated secretion was studied when basal levels were again reached (0.04 mg/kg/hr. i.v.). When max response was reached the infusion was maintained for one additional hr. There was no response to meat extract in 5 normals and 5 patients. The duration of the response in those subjects responding was similar for both normals and patients, although the response of the patients was approx. twice the normal. There was a high correlation between basal secretion and the response to meat. The response to meat extract and the response to histamine stimulation showed good repetition in 6 subjects and poor in 4. In 22 patients stimulated with meat after vagotom 8 showed free acid but at lower levels than in preoperative testing. All showed a lesser but distinct effect of histamine. One patient was studied who secreted 75-100% of the acid secreted in response to histamine when stimulated with meat extract even after vagotomy. Recurrent ulceration in this patient was considered due to antral secretion. It is suggested that one meat extract test provides a useful tool for postoperative (vagotomy) studies of antral functioning.

5699 GASTRIC BLOOD FLOW AND SECRETION IN CONSCIOUS DOGS. (E.) Swan, K. G. (Cornell U. Med. Coll., New York City) and E. D. Jacobson. Amer. J. Physiol. 212(4):891-896, 1967.

The relationship between gastric blood flow and secretion was studied in conscious dogs. When either extracted porcine gastrin or a related, synthetic pentapeptide were admin., each in a wide range of increasing doses, there was a progressive rise in the secretory rate from Heidenhain pouches. After gastrin stimulation, mucosal blood flow, determined by the clearance of aminopyrine, increased as the secretory rate increased, except at the highest rates of secretion. Stimulation with pentapeptide was followed by parallel increases in mucosal blood flow and secretory rate over the entire secretory range. Total blood flow was measured by an electromagnetic blood flowmeter chronically implanted on the artery supplying the pouch; it was not altered by either stimulant of gastric secretion. Secretory rate, mucosal blood flow and arterial inflow were increased when dogs with gastric fistulas were stimulated with either 2-deoxy-D-glucose or insulin. All 3 measurements were reduced by atropine and by an anesthetizing dose of pentobarbital.

5700 PARASYMPATHETIC ACTION ON GASTRIC BIOELECTRIC POTENTIAL IN RATS. (E.) Ridley, H. A. (U.S. Naval Radiol. Def. Lab., San Francisco, Calif.), B. E. Vaughan and J. T. Cummins. Canad. J. Physiol. Pharmacol. 45(2): 281-290, 1967.

Female rats were sacrificed by ether anesthetization, complete decapitation, or stunning. The gastric bioelectric potential *in vitro* was consistently lower in the stunned rats; this depressed potential was prevented by vagotomy and by atropine, either inj. s.c. or directly instilled. Transmural potential and short-circuit current were sharply decreased by 50% when the soln. bathing the mucosal surface was made 10^{-2}M in acetylcholine; there was no detectable effect on transmural conductance. Inhibition of potential was proportional to acetylcholine conc. from 10^{-5} M to 10^{-2} M. Partial recovery was demonstrated by rinsing and replacing soln.; at 10^{-4} M, atropine irreversibly blocked such inhibition. At 10^{-3} M, tubocurarine did not change the response when added before acetylcholine, but at 10^{-4} M physostigmine enhanced the effect of acetylcholine. The acetylcholine analogs, acetylthiocholine, carbamylcholine and acetyl-β-methylcholine (all at 10^{-3} M) reduced potential, as did acetylcholine at 10^{-3} M. Carbamylcholine, which is not appreciably hydrolyzed by acetylcholinesterase, had only slightly greater effect than acetylcholine. Bioelectric potential in these studies was altered without any change in the acid secretion rate. These findings support other studies which demonstrated independence in the isolated rat stomach of electrical and acid secretion parameters.

5701 EFFECT OF INTESTINAL REVERSAL AND MASSIVE RESECTION ON GASTRIC SECRETION. (E.) Grundberg, A. B. (VA Hosp., Des Moines, Iowa), A. S. Lopez and L. R. Dragstedt II. Arch. Surg. (Chicago) 94(3):326-329, 1967.

Reversal of 8-cm jejunal segments produced a slight increase in gastric secretion of HCl in Heidenhain pouch dogs. Postoperative Ba motor meal X-ray studies confirmed an av. increase in gastric and small intestinal emptying times. Subsequently 75% small intestinal resections distal to the reversed segments were performed, with an increase in gastric secretion in 8 of 9 dogs. The role of gastric acid hypersecretion is discussed, and it is proposed that vagotomy and pyloroplasty may be preferred to a reversed small intestinal segment in controlling gastric acid hypersecretion and wt. loss after massive intestinal resection. In clinical practice, a combination of the 2 procedures is probably the best treatment for a patient with massive intestinal resection, providing his condition will allow it.

5702 THE EFFECT OF COMPLETE THORACIC-DUCT LYMPH DIVERSION ON GASTRIC SECRETION IN DOGS. (E.) Yakimets, W. W. (U. Alberta, Edmonton, Canada) and G. F. Bondar. Canad. J. Surg. 10(2):218-222, 1967.

Mongrel dogs of both sexes were equipped with Heidenhain pouches; gastric secretion was determined after they had been divided into 3 groups: 1) fasted dogs without lymph diversion; 2) fed dogs without lymph diversion; and 3) fed dogs with complete thoracic-duct lymph diversion. Protein infusion into the stomach increased secretions from a Heidenhain pouch to nearly twice the baseline level, suggesting (at least in part) a hormonal mechanism. A gastric secretagogue must therefore be conveyed either by the portal venous system, the lymphatic system, or both. Complete diversion of thoracic duct lymph caused a markedly significant decrease in Heidenhain pouch secretion. This suggested 2 possibilities: 1) that fasting thoracic duct lymph conveys a potent gastric secretagogue(s) in quantities sufficient to maintain a steady baseline secretion (the quantity of this secretagogue was greatly increased postprandially); and 2) that the lymphatic system may possibly be important in the hormonal control of gastric secretion since it bypasses the detoxifying capacity of the liver; this was confirmed by the observation that Heidenhain-pouch secretory activity was minimal in lymph-diverted dogs after feeding. Histamine did not appear to be the secretagogue in lymph, since lymph histamine levels did not rise postprandially. Systemic infusion (i.v.) of exogenous histamine in amounts approx. 4 times or more greater than that diverted in lymph was required to stimulate gastric secretion. The gastric secretagogue transported in thoracic duct lymph may be gastrin. Evidence that most of the gastrin or other gastric secretagogues are inactivated by the liver was supported by the marked reduction in Heidenhain-pouch secretion in lymph-diverted dogs, compared to fasted controls.

5703 PRELIMINARY COMMUNICATIONS OF THE EFFECT OF GASTRIN II ON ACID SECRETION IN CONSCIOUS RATS WITH CHRONIC GASTRIC FISTULA.

(E.) Halter, F. (Western Gen. Hosp., Edinburgh, Scotland), P. C. Ganguli, M. Marshall and G. P. Crean. Gastroenterologia (Basel) 106(4): 194-201, 1966.

Male Sprague-Dawley rats were equipped with gastric fistulas made of acrylic acetate. No tests were made for at least 2 wk. following operation. During testing the animals were restrained in Bollman-type cages mounted to rotate to facilitate stomach drainage; the rats were starved 16-20 hr. before testing. At the beginning of the test (6 hr.) a hypodermic needle was placed s.c. and left in place for the inj. of gastrin. The stomach was washed out with water. Secretions were collected at 0.5 hr. intervals; after 4 controls gastrin was inj. and collections were made for 4 hr. When saline was inj. secretion remained steady (10 μEq/30 min.) for the period of 6 hr. The response to gastrin was rapid, the "peak" being reached in 1 hr.; the duration of the response was about 2.5 hr. There was considerable variation between rats; peak effect to 2 μg of gastrin ranged from 120-190 μEq. Data presented for one rat show a linear relationship between the secretory response and log dose. With the data gathered, however, it was not felt possible to define the dose of gastrin evoking a max. secretory response in the rat.

5704 EFFECT OF SECRETIN ON HISTAMINE AND GASTRIN-INDUCED GASTRIC ACID SECRETION.

(E.) Gurll, N. J. (U. California Sch. Med., San Francisco), O. Peloso and W. Silen. J. Surg. Res. 6(9):373-378, 1966.

Heidenhain pouches were prepared in 9 dogs and antrectomy was performed in 6 dogs after completion of baseline secretory tests. Food was withheld 18 hr. pretest. Histamine (0.24 mg/hr.) or gastrin (28.8 g/hr.) were infused i.v. When vol. of secretion from the pouch was stable 75 U of secretin were inj. i.v. Secretions were collected every 15 min. for the duration of the study (4-5 hr.). Secretin failed to inhibit pouch secretion during histamine infusion in 16 of 17 experiments before antrectomy, but did produce a small increase. Following antrectomy histamine produced a larger secretory effect and the effect of secretin was even greater. Secretory output due to stimulation by gastrin was significantly inhibited by secretin both before and after antrectomy; both the secretory effect of gastrin and the inhibition produced by secretin were greater after antrectomy. Before antrectomy secretin inhibited pouch secretion by 18.2%; after antrectomy inhibition was 54.7-56.1%. It is concluded that at least some degree of endogenous inhibition of gastrin and histamine-induced Heidenhain pouch secretion is exerted by the antrum.

5705 THE EFFECTS OF VARYING ATMOSPHERIC CONCENTRATIONS OF CARBON DIOXIDE AND OXYGEN ON GASTRIC ACID SECRETION IN THE PYLORUS-LIGATURED RAT.

(E.) Breen, J. J. (U. Minnesota Med. Sch., Minneapolis), W. P. Ritchie, Jr., J. P. Delaney and O. H. Wangensteen. J. Surg. Res. 7(1):10-16, 1967.

Groups of 10-wk.-old rats (250-300 g) were subjected to pyloric ligature under ether anesthesia after a 48-hr. fast. Rats were placed three to a cage and approx. half the rats were exposed to an atmosphere of room air, the other half to an atmosphere containing varying proportions of CO_2, O_2 and N_2. Conc. of gases in the experimental groups were monitored continuously. After four hr. the rats were decapitated, blood samples taken and the stomachs removed. Gastric contents were assayed for acidity and pepsin activity. Rats exposed to 20% CO_2, 20% O_2 and 60% N_2 showed reduction in vol., free acid and total acid compared to rats in room air. Rats in 10% CO_2, 20% O_2 and 70% N_2 or in 5% CO_2, 20% O_2 and 75% N_2 did not differ from controls. Blood pH levels were reduced in both 10% and 20% CO_2 groups. pCO_2 values were raised in all groups. Rats exposed to 10% O_2 and 90% N_2 showed reduction in vol. and acid. An atmosphere of 10% O_2, 5% CO_2 and 85% N_2 showed no change in secretion; 20% CO_2 and 80% O_2 reduced the vol. and acidity of secretion. It is concluded that hypercapnia and hypocapnia are responsible for reductions in acid secretion, and that hyperoxia and hypoxia of moderate degree are not. No significant alteration in pepsin output was detected.

5706 INHIBITORY ACTION OF CHOLECYSTOKININ ON ACID SECRETION FROM HEIDENHAIN POUCHES INDUCED BY ENDOGENOUS GASTRIN.

(E.) Brown, J. C. (U. British Columbia, Vancouver, Canada) and D. F. Magee. Gut 8(1):29-31, 1967.

Five dogs were prepared with Heidenhain fundic pouches and denervated antral pouches. Gastrin was released by perfusing the denervated antrum with 5% peptone or a 0.1% acetylcholine chloride soln. The Heidenhain pouch was perfused with 25 ml saline, and washed with saline at the end of each 15-min. collection period. When acid secretion from the Heidenhain pouch reached a plateau, cholecystokinin was infused i.v. 1.0-2.0 U/kg. Peptone (5%) pouch infusion usually achieved a plateau of acid secretion after 1.5-2 hr. Admin. of cholecystokinin depressed acid output even though peptone stimulation was continued; the depression was observed in the econd or third 15-min. period following inj. of holecystokinin. The mean inhibition was 72.6%. erfusion of the pouch with acetylcholine prouced almost identical effects as peptone, and a imilar inhibition was produced by cholecystokinin. t is concluded that cholecystokinin produces a rofound inhibition of gastric secretion induced y endogenous gastrin, inhibiting acid output roduced during the hormonal phase of gastric ecretion.

707 EFFECT OF COMBINED BRAIN STIMULATION ON GASTRIC SECRETION, ACIDITY AND OTASSIUM CONCENTRATION IN CATS. (E.) Feldman, . (Hadassah U. Hosp., Jerusalem, Israel), J. ajsbort and D. Birnbaum. Brain Res. 4(1): 03-106, 1967.

Three groups of cats were used to study the effects of dorsal hippocampus stimulation alone, or anterior hypothalamic or hippocampal stimulation immediately preceding posterior hypothalamic stimulation on gastric secretion. All studies were done in the anesthetized preparation. The technics used were previously described. Posterior hypothalamic stimulation increased gastric secretion. With anterior hypothalamus or hippocampal stimulation, or when posterior hypothalamic stimulation followed, no effects on secretion were produced. Combined anterior and posterior hypothalamic stimulation produced a lower rate of secretion than that following anterior hypothalamic stimulation alone. Only posterior hypothalamic stimulation increased acid output. Anterior hypothalamic or hippocampal stimulation inhibited acid output. Combined anterior and posterior hypothalamic stimulation caused a smaller acid output compared to anterior hypothalamic stimulation alone. Posterior hypothalamic stimulation increased K conc.; hippocampal or hippocampus posterior hypothalamic and anterior posterior hypothalamic stimulation decreased K conc. It is concluded that the anterior hypothalamus and dorsal hippocampus modify the effects of the posterior hypothalamus on gastric secretion.

5708 INFLUENCE OF ROUTE OF ADMINISTRATION ON THERAPEUTIC RATIO OF ATROPINE IN SHAM-FED DOGS. (E.) Kubin, R. H. (U. Kansas Med. Ctr., Kansas City), W. R. Keeler and A. P. Klotz. Amer. J. Dig. Dis. 12(4):363-370, 1967.

Three dogs with esophagostomy and gastrostomy were sham fed in a standardized manner at various intervals following the admin. of atropine sulfate or saline. The method of determining salivation and gastric secretion is described in the following paper. Atropine was admin. intragastrically, by a single i.v. dose, or by continuous i.v. infusion. Varying doses were admin. to allow estimation of doses producing 50% inhibition of both salivary and gastric secretion. The route of admin. had a profound effect on salivary and gastric 50% doses. At all time periods the salivary and gastric 50% doses for intragastric doses were 4 times the single i.v. doses. For single i.v. doses the gastric 50% doses were 2-3 times larger than the corresponding gastric 50% doses for continuous i.v. doses. A therapeutic ratio relating gastric and salivary doses in all cases decreased as the interval after dosing increased. The ratio for continuous i.v. admin. was the highest of any route at 40 and 100 min. The authors suggest that continuous i.v. infusion of atropine may be an effective method of inhibiting gastric secretion without materially inhibiting salivary secretion, at least for moderate periods of time.

5709 NONPARALLEL GASTRIC AND SALIVARY GLAND INHIBITION PRODUCED BY ANTICHOLINERGIC DRUGS IN SHAM-FED DOGS. (E.) Kubin, R. H. (U. Kansas Med. Ctr., Kansas City), W. R. Keeler and A. P. Klotz. Amer. J. Dig. Dis. 12(4):371-378, 1967.

Three mongrel dogs were prepared by esophagostomy and gastrostomy. The proximal esophageal stump was sutured to the skin of the neck to form an esophagocutaneous fistula; the distal stoma was ligated to prevent food from entering the stomach during sham feeding. The dogs were maintained by intragastric feeding. Sham feeding was done only once daily. Gastric juice collections were made for 5-15 min., starting 5 min. after the start of sham feeding. The drugs were inj. 20-160 min. preceding sham feeding. Saliva wt. was determined by careful weighing of the sham meal before and after feeding. Dogs were allowed to reingest the esophagostomy effluent for a 5-min. period. Atropine sulfate and heteronium bromide were given in increasing doses until 50% inhibition of control levels was reached. The ratio between the 50% doses for inhibiting salivation and gastric secretion ranged from 4.2 at 20 min. to 0.93 at 160 min. for atropine. The increase in dose necessary for salivary blockade approx. doubled or trebled in 160 min. The gastric dose increased by 10-fold. The same general pattern was seen when heteronium bromide was tested. With atropine at 20 and 40 min. gastric secretion was more sensitive than salivary secretion to anticholinergic inhibition while at 100 and 160 min. the sensitivity was approx. equal. The authors conclude that gastric inhibition and salivary inhibition with the drugs studied are not parallel processes.

5710 FREEZING OF THE INTACT RAT STOMACH: AN INDICATION OF THE BIOLOGIC POTENTIAL OF THE TECHNIC. (E.) Ritchie, W. P., Jr. (U. Minnesota Med. Sch., Minneapolis), J. J. Breen and O. W. Wangensteen. Amer. J. Dig. Dis. 12(4):379-388, 1967.

The technic for freezing the rat stomach as previously described was used in the present study preceding pyloric ligation or histologic study. Freezing of the stomach was carried out under light ether anesthesia. The freezing balloon was placed in the stomach through a stab wound in the anterior wall of the ruminal portion of the stomach. Group A consisted of 35 rats whose stomachs were frozen at -5°C for 3 min., Group B, 11 rats at -10°C for 3 min., and Group C, 7 rats at -15°C for 3 min. Pyloric ligation for 4 hr. in control rats yielded an av. vol. of 8.3 ml, 0.62 mEq free acid, and 0.97 mEq total acid. One wk. after freezing rats from Group A av. 1 ml vol. with no free or total acid, 2 wk. later there was no change, 3 wk. later the av. vol. was 2.1 ml and 0.012 mEq free acid and 0.043 mEq total acid; similar levels were found up to 12 wk. after freezing. Surviving rats in Groups B and C at 12 wk. produced little or no free or total acid; vol. were decreased but approx. normal. In Group A 14 of 35, Group B 4 of 11, and Group C 6 of 7 rats died. Microscopically the stomachs in Groups A and B revealed a reduction in parietal and chief cells and an increase in mucus-secreting elements, generally paralleling the degree of hypothermia. The authors conclude that cold under appropriate conditions can markedly alter the ability of the stomach to secrete acid.

5711 RELATION OF ANTRAL pH TO GASTRIN RELEASE AND FUNDAL pH IN DOGS. (E.) Posey, E. L., Jr. (U. Mississippi Sch. Med., Jackson) and H. Franklin. Amer. J. Dig. Dis. 12(4):356-362, 1967.

Four dogs were prepared with Heidenhain pouches and cannulas placed in the fundus and antrum. Fasting pouch output was measured for 1 hr. Changes in pH in the fundus and pouch, and pouch acid production were studied while antral pH was varied by perfusion with various soln. which were allowed to drain into the duodenum. With antral pH below 1.8 no appreciable secretory effect on the pouch was found. A transition was encountered with antral pH of 1.8-3.0 in which relatively small and variable amounts of pouch acid were produced. Above an antral pH of 3.0 a significant secretory effect was noted that did not increase with further increases in antral pH. Fundal and pouch pH were relatively high and had little relationship to one another when antral pH was less than 1.8. The values fell and became more closely associated at the antral transition zone of pH 1.8-3.0. Above an antral pH of 3.0, fundus and pouch pH decreased and fluctuated in a parallel manner. Pouch pH was consistently below fundal pH. The conventional use of antacids in the treatment of peptic ulcer theoretically can be expected to result in further acid secretion through stimulation by gastrin by the antral pH sensitive mechanism.

5712 SECRETORY RESPONSE TO SUSTAINED HISTAMINE STIMULATION OF THE ISOLATED CANINE STOMACH. (E.) Dritsas, K. G. (U. Alberta, Edmonton, Canada), G. F. Bondar and K. Kowalewski. Brit. J. Surg. 53(9):798-802, 1966

The histamine-stimulated dog stomach in a homologous ex vivo preparation was capable of secretory function for as long as 16 hr. The secretory pattern in response to sustained i.v. (24 μg/min.) and intra-arterial (9.6 μg/min.) stimulation is presented. With regard to electrolyte composition of gastric juice, Cl varied with acidity, Na varied inversely with acidity and K followed a depletion course. Secretory vol. of over 2 ml/min. and HCl conc. over 155 mEq/liter were obtained. Contrary to various types of responses previously reported, this study demonstrated only 1 type of response characterized by a gradual increase in function, a plateau and a gradual decline. Pepsin conc. decreased during histamine stimulation; absolute pepsin output increased well above basal levels during sustained histamine stimulation. The washout theory with regard to pepsin behavior in response to histamine stimulation cannot explain a 16-hr.-long sustained increase in pepsin output, and it is therefore concluded that histamine stimulates pepsin secretion in the denervated canine pouch. The ulcerogenic effect of low arterial CO_2 observed by others was confirmed. Ventilation of an oxygenator dog with 100% O_2 produced an arterial CO_2 pressure of 18 mm Hg, and resulted in multiple superficial ulcers and petechial hemorrhages in the gastric mucosa of the isolated stomach, including the antrum. Ventilation with 97% O_2 and 3% CO_2 produced an arterial CO_2 pressure of 36 mm Hg and was obviously protective to the gastric mucosa.

5713 OUR IMPRESSIONS ON THE FORM, POSITION, MUCOSAL SURFACE AND THE SECRETORY FUNCTION OF THE STOMACH IN YOUNG ALGERIAN SOLDIERS. (Fr.) Kovatchev, D. and M. Younachkov Rev. Int. Serv. Sante Armees 39(11):773-775, 1966.

Of 50 young Algerian men (age 18-24 yr.) without dyspeptic symptoms, 20 (40%) showed gastric hypotonia, 2 (4%) showed hypertonia and the other 28 (56%) were normotonic. Some degree of mucosal hypertrophy was noted in 28%. Gastric acidity was normal in 46% (23 cases); 10% (5 cases) showed hyperacidity and 40% (20 cases) showed hypoacidity (HCl levels were normal in 8; both total acidity and HCl levels were subnormal in 12 cases). Achylia from the presence of duodenal juice in the stomach was noted in 2 cases (4%). This marked deviation from normal in asymptomatic subjects may be considered physiological; no explanation of the phenomenon could be made.

5714 PLACENTAL TRANSFER OF GASTRIC ANTIBODIES. (E.) Fisher, J. M. (Stanford U. Sch. Med., Palo Alto, Calif.) and K. B. Taylor. Lancet 1(7492):695-698, 1967.

mbilical cord-serum was obtained at the time of
elivery from 3 young women (29-35 yr. old)
nown to have gastric mucosal disease and
irculating gastric mucosal antibodies. All 3
ubjects had circulating parietal-cell anti-
odies of the IgG class, and one had IgA anti-
ody in addition. Cord-serum of all infants had
nly IgG antibody. Positive complement-fixation
iters were found in all maternal sera and were
lso found in the cord. The cord-sera of 2
nfants had higher titers than corresponding
aternal sera, and in 1 case it was considerably
igher. Serial studies of the sera of 2 infants
howed progressive decline of the complement-
ixation titer; this was compatible with the
alf-life of γ-globulin and suggested that any
etectable antibody was of maternal origin. In
2 cases, the mothers had other detectable anti-
odies (thyroid microsomal antibody in one,
intrinsic-factor antibodies in the other) that
were also found in the cord serum. Gastric
aspirates were obtained at birth and 3-6 wk.
afterward from 2 infants, but no antibodies
were detected in their gastric juice or that of
their mothers. By indirect means, intrinsic
factor was detected at 3 wk. of age in the
gastric juice of 1 infant, and by direct means
at birth and at 6 wk. of age in another infant.
In the child with circulating intrinsic-factor
antibodies, intrinsic factor could be detected
at 3 wk. in the gastric juice, although he had a
high level of circulating antibody at the time.

5715 STUDIES ON SECRETORY VARIATIONS INDUCED BY A NEW PREPARATION WHICH STIMULATES GASTRIC SECRETION.

(It.) De La Pierre, M. (U. Turin, Italy) and C. Saracco. Minerva Gastroent. 12(1):24-27, 1966.

The effects on gastric secretion of a new drug containing gelatin and protease obtained from *Aspergillus oryzae* were studied in 40 patients of both sexes (30-76 yr. old) with dyspeptic disturbances but no clinical, X-ray, or laboratory evidence of organic gastric disease. A suspension of the drug was prepared by adding 4 tablets to 50 ml of lukewarm water and admin. by gastric tube. After 1 hr., the vol. of gastric juice secretion was increased 47.8% and free acid levels increased 49.1% in 34 of 40 patients; both values were statistically significant with respect to controls. Total acid content was increased (36.4%) in 34 patients and slightly decreased in 6. Free acid output increased 116% at a pH of 3.5 and 96.4% at a pH of 7.5; 36 patients showed an increase and 4 a moderate reduction. Absolute values of acid output increase was greatest in patients who showed normal acidity before the test than in those who were hyper- or hypoacidic. The percentage increase in acid output was proportionally greater in hypoacidic patients than in normo- or hyperacidic patients. The gastric secretory response to the drug lasted more than 60 min. Overall results indicate a positive response in 85%, with 15% either showing no change or reduced acid output. No subjective disturbances or side effects were observed.

5716 SECRETORY FUNCTION OF THE STOMACH IN PARATHYROIDECTOMIZED RATS.

(Rus.) Skatkov, M. E. (Inst. Normal Pathol. Physiol., Acad. Med. Sci., Moscow). Biull. Eksp. Biol. Med. 62(11):50-51, 1966.

Studies on the secretory function of the stomach in parathyroidectomized and normal white rats revealed that parathyroidectomy leads to increased total and free acidity of the gastric juice. However, the removal of the glands did not affect the vol. of the juice excreted. Admin. (s.c.) of histamine (0.5 mg/animal) further increased the free and total acidity, but decreased the proteolytic activity of the gastric juice of both parathyroidectomized and normal rats by approx. 20% and 60%, resp. These studies were begun one wk. after removal of the gland and continued for 6 mo.

5717 ANALYSIS OF CHLORINE EXCRETION FUNCTION OF THE STOMACH IN MAN AND IN EXPERIMENT.

(Rus.) Torosov, T. M. (Kirov Milit. Med. Acad., Leningrad, USSR). Biull. Eksp. Biol. Med. 62(11):20-23, 1966.

The conc. of neutral chlorides in gastric juice of man or dog was correlated with its acidity and with the conc. of chlorides in the blood. The conc. of neutral chlorides in the gastric juice from the fasting stomach varied in parallel with the level of chlorides in the blood. No correlation was found between the conc. of neutral chlorides in gastric juice from the fasting stomach and its acidity. As secretion began, the conc. of neutral chlorides in the gastric juice gradually decreased and became inversely proportional to the acidity of the juice. These relationships indicate that HCl is synthesized extracellularly in the stomach. With respect to chlorides, the gastric juice represents a mixture of the secretions of the chief and auxiliary cells, containing approx. 100 mEq chlorides/liter, and secretions of border cells, with chloride content varying between 0-200 μEq/liter.

5718 THE ACTION OF 10(α-DIMETHYLAMINOPROPIONYL) PHENOTHIAZINE METHOBROMIDE UPON MAXIMUM GASTRIC SECRETION STIMULATED WITH THE HISTAMINE AND HISTALOG.

(Sp.) Laudano, O. M. (Fac. Med. Sci., Rosario, Brazil). Prensa Med. Argent. 53(29):1604-1606, 1966.

Two groups of patients were studied. Group 1 consisted of 25 subjects (19 men, 6 women; 21-43 yr. old; 14 healthy normals, 11 with duodenal ulcers). The action of 10(α-dimethylaminopropionyl) phenothiazine methobromide on gastric secretion stimulated with an augmented histamine test was studied. Histamine (i.m.;

0.5 mg/kg) and an antihistamine were used. The title compound decreased gastric secretion. Side effects included dryness of the mouth, mydriasis, tachycardia and visual disturbances. In Group 2 (7 men, 3 women; 19-51 yr. old; 6 healthy normals and 4 with duodenal ulcer), no antihistamine was given and the histamine dose was 2.0 mg/kg. The drug did not decrease the gastric stimulation previously stimulated by the augmented histamine test. It is concluded that 10(α-dimethylaminopropionyl) phenothiazine methobromide is a strong anticholinergic agent with a very small ganglionic-blocking action.

5719 STUDY ON GASTRIC SECRETORY ACTIVITY BY THE CARBOWAX-CONGO RED METHOD. (Jap.) Konaka, K. (Kumamoto U. Med. Sch., Japan), T. Shudo, M. Okabe, Y. Matsuoka and T. Yasumitu. Kumamoto Igakkai Zasshi (J. Kumamoto Med. Soc.) 41(1):32-40, 1967.

A mixture of Carbowax and Congo Red (20:1) was spread on the exposed gastric mucosa of anesthetized rats, and the change in color of the Congo Red caused by gastric acid secretion was observed. After the inj. of histamine (5 μg/150 g i.v.; 100 μg/150 g s.c.), synthetic gastrin active group (synthesized by Esai Co., Ltd.: TFA-NH_3-TRY-MET-ASP-PHE-NH_2: 50 μg/150 g i.v.) or swine pancreas extract prepared by the authors with the use of AE-cellulose column chromatography (AE-FH) (70-80 μg/150 g i.v.), increase of gastric secretory activity was observed. The increase was found in 2-3 min. after inj., and continued for more than 60 min., with histamine, for around 45 min. with gastrin active group and for 20-30 min. with AE-FH. A marked increase in secretion of free acid and total acidity was observed after the i.v. infusion of 50 ml of 50-fold diluted soln. of AE-FH for 60 min. in dogs with gastric cannula, both conc. increasing to 15-18 times the initial level for 30-120 min. after the start of infusion.

5720 HETEROGENEITY AND SEQUENCE OF APPEARANCE OF RABBIT ANTIBODIES TO HOG INTRINSIC FACTOR. (E.) Samloff, I. M. (U. Rochester Sch. Med. Dent., New York) and E. V. Barnett. J. Immun. 98(3):558-567, 1967.

Primary and secondary immune responses of rabbits to hog intrinsic factor concentrates were studied with the radioimmunoelectrophoretic method. Three anti-hog intrinsic factor concentrate-^{60}Co-B$_{12}$-binding antibodies were detected. When a goat anti-rabbit serum was used as a developer γM and γG antibodies were found to appear simultaneously, 7-8 days after primary immunization. When the developing serum was not used, an illusion suggesting the later appearance of γG antibody was noted. These findings offer further evidence for the concurrent synthesis of γM and γG antibodies after primary immunization. The data additionally suggest that early γG anti-hog intrinsic factor antibody forms a soluble or easily dissociable complex with hog intrinsic factor concentrate-^{60}Co-B$_{12}$, while later γG antibody forms an insoluble or less readily dissociable complex with the radioactively labeled antigen. In 2 of 3 rabbits, a third hog intrinsic factor concentrate-^{60}Co-B$_{12}$-binding antibody appeared from 3-4 wk. after primary immunization. This antibody migrated slightly faster than γG on electrophoresis in agar gel, was eluted with γG-globulins from Sephadex G-200 and was resistant to 2-mercaptoethanol. After secondar immunization there was an anamnestic response for the synthesis of all 3 antibodies.

5721 SEPARATION OF VITAMIN B12-BINDING PROTEINS OF SERUM, GASTRIC JUICE AND SALIVA BY RAPID DEAE CELLULOSE CHROMATOGRAPHY. (E.) Retief, F. P. (Mount Sinai Hosp., New York City), C. W. Gottlieb, S. Kochwa, P. W. Pratt and V. Herbert. Blood 29(4):501-516, 1967.

A technic of DEAE cellulose chromatography is presented by which the principal vitamin B$_{12}$ binders in serum, gastric juice and saliva may be separated in less than 2 hr. into 2 distinct fractions, 1 containing α-globulin binder and the other containing β-globulin binder. Typica elution patterns of α-globulin and β-globulin B12 binders from normal (80% β, 20% α), pernici anemia (66.6% β, 33.3% α) and chronic myeloid leukemia (75% α) sera are presented. Chromatography of normal gastric juice produced 2 peaks of B$_{12}$-binding material, 1 containing all the intrinsic factor B$_{12}$ binder (as well as some non-intrinsic factor binder), and the other consisting almost exclusively of non-intrinsic factor B$_{12}$ binders. Pernicious anemia gastric juice also produced 2 peaks, but intrinsic factor was lacking. Saliva had 1 main peak of B$_{12}$-binding material which seemed to correspond to the non-intrinsic factor binder of normal gastric juices; both of these eluted with the α-globulin fraction.

5722 CHOLECYSTOKININ--PANCREOZYMIN (CCK-PZ). (Sw.) Jorpes, E. (Karolinska Inst., Stockholm) and V. Mutt. Nord. Med. 77(8):237-242, 1967.

Cholecystokinin (CCK) was isolated from the first meter of the small intestine of 20 hogs, cooked, frozen and ground (1.400 g) through a series of extractions, adsorptions, elutions, precipitations and fractionations in 9 steps. The sixth step resulted in 20 g of material with 20 Ivy dog U of CCK/mg and 80 Crick, Harper and Raper pancreozymin (PZ) U/mg; step 7 yielded 750 mg of material with 250 U of CCK and 1000 U of PZ/mg; step 8 yielded 60 mg of material with activities of 1500 and 6000 U/mg of CCK and PZ, resp. The last step resulted in 12 mg of material with 3,000 U of CCK and 12,000 U of PZ/mg. During the steps in purification he CCK and PZ activity maintained a fixed atio of 1:4. The activity per mg of the final reparation was 10,000 times that in Crick, arper and Raper's original PZ preparation. It s concluded that both hormonal activities are xerted by the same compound. A review of the hysiological effects of CCK and PZ is presented ith clinical applications of the hormonal ctivities in cholecystography and cholangiog- aphy and in the combined PZ and CCK test for he diagnosis of chronic pancreatitis and cancer f the pancreas and biliary system. CCK has eplaced the fat meal in cholecystography technic n Sweden. CCK (250 Ivy dog U) has been used n biliary surgery.

723 A CHEMICAL, IMMUNOLOGICAL AND ELECTRON-MICROSCOPIC STUDY OF CENTRIFUGED HUMAN UBMAXILLARY SALIVA. (E.) Caldwell, R. C. (U. labama Med. Ctr., Birmingham) and J. M. hackleford. Arch. Oral Biol. 12(3):333-340, 967.

uman submaxillary saliva was collected from 4 ealthy male subjects; it contained a variety of ytoplasmic fragments which were demonstrated by lectron microscopy of the sediment from saliva entrifuged at 59,700 g. This procedure yielded a viscous material (salivary gel) containing a onsiderable number of electron-dense granules and vesicles varying in size from approx. 1.0 μ to as small as 250 Å. Vesicles were found free or as inclusions in fragments of cytoplasmic material containing partially disintegrated mitochondria and membranes. Blebs of cytoplasm were occasionally enclosed by structures that were membranous in appearance. Chemical analysis of salivary gels obtained from 1 secretor and 1 nonsecretor of blood group substances demonstrated that the gels contained considerably less than 10% of the total salivary protein. Fucose, sialic acid, hexose and hexosamine were also found in the gels. The absolute and relative amounts of carbohydrate differed in salivary gels from the secretor and the nonsecretor of blood group substances. Blood group assays suggested that blood group substances A, Le(a) and Le(b) were conc. in the salivary gel.

5724 RECORDING THE PATTERN OF SALIVARY FLOW. (E.) Mason, D. K. (Western Infirm., Glasgow, Scotland), R. M. Harden, D. Rowan and W. D. Alexander. J. Dent. Res. 45(5):1458-1463, 1966.

An instrument designed around 3 photoelectric detectors into which were inserted polyethylene cannulae conveying saliva from the patient was used. Each detector consisted of a glass-drip chamber, a photo-transistor and a lamp arranged so that the beam of light falling on the phototransistor was interrupted by the falling drop. Saliva was collected from volunteers by use of a modified Carlson-Crittenden cup, cannulation of the submandibular duct, or by the use of a segregator appliance. Lemon juice, salt, beef bouillon cubes, fruit-flavored candy and paraffin-wax were used as stimulants. Iodine was estimated in samples of the saliva using a chloric acid digestion method. It was found that at any one flow rate the drop size remained relatively constant. An inverse relation was found between the salivary iodide conc. and the rate of salivary flow. Swallowing was found to produce a transient increase in flow rate. The effect of a severe stimulus, lemon juice, was found to persist for some time after the stimulus had stopped. Irregular flow rates caused by swallowing, irregular application of stimulants were found to yield inaccurate results using iodine secretion as a dependent variable.

5725 THE EXPERIMENTAL PRODUCTION OF WATERY VACUOLATION IN THE ACINAR CELLS OF THE SUBMANDIBULAR GLAND. (E.) Tapp, R. L. (U. Cambridge, England) and O. A. Trowell. J. Physiol. (London) 188(2):191-205, 1967.

The vacuoles were cytoplasmic, membrane-walled and 2-20 μ in diameter; they were visible in living cells and appeared to contain a watery fluid. Vacuolation occurred regularly under 3 experimental conditions: 1) in vivo, during secretion; 2) after death, in animals killed by anoxia; and 3) in vitro, under anoxic conditions. By means of in vitro experiments, it was demonstrated that vacuolation occurs only when the cells are both anoxic and exposed to an excess of extracellular fluid containing Ca and HCO_3; it was also shown that vacuolation is reversible in O_2 and that both its development and recovery are temperature-dependent. Evidence is presented suggesting that the vacuolation is not caused by simple osmosis, that it is not a degenerative or necrotic change and that it is accompanied by the entry of fluid into the cells. The mechanism of vacuolation and its possible relation to secretion are discussed, and it is suggested that vacuolation represents an imbalance between the ingestion and secretion of water and salts. Similar vacuoles, apparently produced by the same mechanism, were seen in the acinar cells of the parotid gland and the pancreas of the rat. The close similarity of this vacuolation to that previously described in rat liver cells was noted.

5726 CHOLERETIC EFFECT OF ATROPINE IN THE RAT: EFFECT ON EXTERNAL PANCREATIC SECRETION. (Fr.) Debray, C. (Bichat Hosp., Paris), C. Vaille, J. De La Tour, C. Roze and M. Souchard. Path. Biol. (Paris) 15(1-2):51-54, 1967.

In urethan-anesthetized rats, doses of atropine causing prolonged respiratory stimulation (30 mg/kg i.v.) and induced a slight, delayed (3 hr.) increase in pancreatic secretion. Bile secretion in control animals decreased 9%; in atropine-treated animals a marked, prolonged choleresis was noted (by 18% at 10 min., 46% at 1 hr., 28% at 2 hr. and 10% at 3 hr.). This choleretic response could not be explained by changes in transhepatic blood flow or by relaxation of the bile ducts (which was weak). It is suggested that atropine stimulates bile production by a direct action on the liver cells.

5727 CHROMATOGRAPHIC BEHAVIOUR OF PANCREATIC AMYLASE. (E.) Szabo, M. T. (U. Budapest, Hungary) and F. B. Straub. Acta Biochim. Biophys. Acad. Sci. Hung. 1(4):379-387, 1966.

Amylase was isolated from pig pancreas and recrystallized from an ammonia soln. or from an urea soln. Chromatography was done on DEAE-Sephadex A-50 (medium) columns equilibrated with either a buffer soln. of pH 7.5 containing 10^{-2} M TRIS-HCl, 10^{-4} M mercaptoethanol, 5 x 10-3 M Ca ions and 2 x 10^{-2} M Cl ions or with a similar soln. without mercaptoethanol. Amylase activity was assayed by Smith and Roe's method. In the absence of mercaptoethanol, amylase crystallized from ammonia soln. was more strongly bound to the ion exchanger than amylase crystallized from urea soln. In the presence of mercaptoethanol several active peaks were obtained, indicating the presence of several active forms of amylase. Under these conditions amylase crystallized from ammonia soln. existed in 2 active forms whereas amylase recrystallized from urea soln. was present in the form of 4 active proteins. It was possible to convert one of the active forms into another by lyophilization with NaCl present. It is concluded that amylase of pig pancreas may exist in different structural forms which are all enzymatically active and which can be separated by chromatography on DEAE-Sephadex column.

5728 THE OUTPUT OF PROTEIN AFTER PANCREOZYMIN. A TEST OF PANCREATIC FUNCTION. (E.) Hanscom, D. H. (VA Hosp., Hines, Ill.), B. M. Jacobson and A. Littman. Ann. Intern. Med. 66(4):721-726, 1967.

Data were collected in 26 normal controls and 63 patients with known pancreatic disease. Duodenal contents were collected by means of a Dreiling double-lumen tube passed into the duodenum under fluoroscopic control. Secretin (1.5 U/kg) was inj. i.v. in 5 min. and six 10-min. specimens collected from the duodenum. At the end of the hr. an infusion of secretin (1.5 U/kg/hr.) was begun and a 1.5 U/kg i.v. dose of pancreozymin was inj. and two 15-min. collections made. Finally 4.5 U/kg of pancreozymin was inj. and two 15-min. collections made. The protein output in the duodenal contents separated controls from chronic pancreatitis patients with little overlap. Other forms of pancreatitis were less often separated from normal but more often with pancreozymin than with secretin. Discriminant function analysis indicated that the pancreozym test separated normal and chronic pancreatitis groups better than the secretin test and with n overlapping. When data from both tests was used there was further diagnostic improvement. It is suggested that if this use of discriminan function analysis is validated, it should be useful in assessing lesser degrees of pancreati injury.

5729 THE ELECTRICAL PROPERTIES OF RESTING AND SECRETING PANCREAS. (E.) Clark, D. G. (U. Newcastle upon Tyne, England), J. R. Greenwell, A. A. Harper, A. M. Sankey and T. Scratcherd. J. Physiol. (London) 189(2): 247-260, 1967.

Electrical properties of the resting and stimulated pancreas were studied in the anesthetized cat. An inverse relationship was found between the frequency of applied alternating current and the resistivity and dielectric constant of the resting pancreas. Resistivity was also affected by the fat content of the gland. The impedance locus of the pancreas was similar to that of other tissues. There was a brief increase, followed by a more marked decrease, in pancreatic conductance and capacitance after i.v. inj. of secretin. The phase of decreased conductance was related to the flow of pancreatic juice. The decrease in conductance and flow was characterized by 2 closely related empirical equations. During secretin stimulation the Na conc. in pancreatic tissue increased and the K conc. decreased. It is suggested that the decreased conductance across the secreting gland was chiefly due to swelling of the secretory cells and, to a minor degree, it is the result of changes in the composition of the secretion in the pancreatic ducts. In the anesthetized cat, the mean half life of the secretory action of secretin is 199 sec.

5730 "NON-PARALLEL TRANSPORT" OF ENZYME PROTEIN BY THE PANCREAS. (E.) Rothman, S. S. (Harvard Med. Sch., Boston, Mass.). Nature (London) 213(5075):460-462, 1967

Secretions were collected directly from the pancreatic duct of rabbits *in vitro* using previously described technics. Collections of secreted fluid were made at hourly intervals. When pancreozymin (6 Ivy dog U of Cecekin/100 ml of water in bath) was added to the organ bath in the *in vitro* studies an enhancement in secretion of trypsinogen was observed while chymotrypsinogen secretion was only slightly elevated. The trypsin/chymotrypsin ratio was doubled compared to controls, suggesting a selective se- cretion of protein by the pancreas. Methacholin chloride added to the organ bath (0.8 mg/100 ml) increased the output of both trypsinogen and chymotrypsinogen. The trypsin/chymotrypsin tio was more variable but there was no nsistent difference from controls. It is ggested that the "selectivity" in the secre- on process most likely occurs in the release ase or in transport of protein from the zymogen anules or cytoplasm into duct lumina. ggested mechanisms were: competition for asma membrane sites by granules containing fferent enzymes, an alternation in the rates enzyme secretion from within the granules, or mpetition for transport sites by the enzymes emselves.

731 THE EXHAUSTION OF THE PANCREOZYMIN EFFECT ON PANCREATIC SECRETION. (Ger.) uhac, I. (First Med. Clin., Acad. Med., Lubeck, ermany) and U. Ritter. Z. Gastroent. 4(5): 79-283, 1966.

e pancreatic ducts of 13 rabbits (3000 g) were atheterized, the secretion collected in 30-min. eriods, and its vol. and α-amylase conc. deter- ined; 3 animals served as controls; the pontaneous secretion was collected for a total f 210 min. Seven animals were inj. i.v. with U/kg and 3 with 4 U/kg pancreozymin at the eginning of each 30 min. period except the irst, during which the basic secretion was ollected. After the experiment pancreatic issue was collected from 11 animals and pre- ared for study. There were large individual ifferences among the animals both in vol. and -amylase conc. of the basic secretion. After 10 min. and 6 pancreozymin inj., the vol. as ell as the amylase level tended to approach the asic values, although still somewhat elevated. he 2 U/kg pancreozymin dose caused an av. ncrease over 180 min. in vol. of about 50% and n av. 4-fold increase in enzyme; 4 U/kg ancreozymin increased the vol. by about 75% of he basic value and the enzyme content 8-fold, v. over the entire experimental period. istological examination of the glands dis- losed no visible decrease in granules; in 2 animals some cellular breakdown and pyknotic uclei were observed; another animal showed some conc. of round cells and edema. However, hese conditions may have been due to causes other than pancreozymin. There was no indication of exhaustion of either fluid or enzyme secretion due to pancreozymin. The effectiveness of pancreozymin seemed to have decreased.

5732 PANCREATIC SECRETION IN RATS WITH PROTEIN MALNUTRITION. (E.) Lemire, S. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and F. L. Iber. Johns Hopkins Med. J. 120(1): 21-25, 1967.

Male Sprague-Dawley rats (40; 135-165 g) were divided into 2 groups; 20 were fed a normal diet and served as controls. The remaining 20 were fed a protein-free diet (corn starch, 70%; alphacel, 15%; vegetable oil, 10%; salt mixture USP XIV, 4%; and cod liver oil, 1%). An additional group of 30 male rats (av. wt. 116 g) was used to assess recovery from the protein-deficient diet. In protein-deficient rats the mean body wt. decreased from 150 to 109 g; total serum protein decreased from 5.8 to 3.8 g/100 ml. In controls, wt. increased from 151 to 270 g, and serum protein did not change significantly from a mean of 6.2 to 5.8 g/100 ml. Protein-deficient rats produced an av. of 0.027 ml of pancreatic juice in 15 min., but control rats produced 0.065 ml in the same time. Protein deficient rats produced 0.41 U of trypsin activity in the stimulated juice, compared to 2.26 U in controls. Bicarbonate production was 0.81 μEq in protein-deficient animals, compared to 2.40 μEq in controls. Histological study showed that secretory granules had largely disappeared in the cellular cytoplasm of protein-deficient rats, in contrast to the normally-fed animals. Data from rats placed on a normal diet after protein deficiency showed that the whole process can be almost completely reversed within a wk. of adequate protein intake.

5759 INTESTINAL DIGESTION OF MALTOTRIOSE IN MAN. (E.) Messer, M. (Roy. Child. Hosp., Melbourne, Australia) and K. R. Kerry. Biochim. Biophys. Acta 132(2):432-443, 1967.

Maltotriose comprised approx. 25% of the end products of the action of duodenal juice on starch *in vitro*; it was largely resistant to the action of the juice but was readily hydrolyzed to glucose by homogenates of the small intestinal mucosa. The rate of hydrolysis of maltotriose by intestinal mucosa was of the same order as that of maltose, isomaltose, lactose, trehalose and sucrose. The Michaelis constant for maltotriose was similar to that for maltose. Mixed substrate incubation experiments indicated that intestinal maltotriase activity is at least partially due to enzymes which also act on sucrose, isomaltose and maltose. Using heat inactivation, intestinal maltotriase activity was separated into 3 distinct fractions; all of these had maltase and isomaltase activity. The pattern of heat inactivation indicated that maltotriase activity is exerted principally by the α-glucosidases designated (Dahlqvist) maltases Ia, Ib and III. Activity of maltotriase was considerably subnormal in duodenal mucosal specimens obtained from patients with congenital absence of maltases Ia and Ib; this was a further indication that these enzymes are involved in the hydrolysis of maltotriose.

5760 METABOLISM OF CIRCULATING DISACCHARIDES IN MAN AND THE RAT. (E.) Weser, E. and M. H. Sleisenger. (New York Hosp., N. Y.) J. Clin. Invest. 46(4):499-505, 1967.

The metabolism of circulating disaccharides was investigated in nonfasting male Sprague-Dawley rats and in adult humans (both normals and patients with untreated celiac disease). No elevation in blood glucose was observed after i.v. infusions of 10 g of either maltose, lactose or sucrose in 4 normal adults. A mean of 6.3 ± 1.39 g of sucrose and 8.7 ± 1.89 g of lactose was excreted in the 24-hr. urine sample. Only 0.11 ± 0.03 g of infused maltose was recovered in the urine, thereby suggesting that maltose was metabolized. Patients with untreated celiac disease excreted 4 times more urinary lactose and sucrose, but not maltose, than normals. After inj. of ^{14}C-labeled lactose and sucrose in rats, 6.2 ± 2.7 and 7.6 ± 2.4%, resp., was oxidized to $^{14}CO_2$ in 24 hr.; 62.1 ± 13.5 and 68.4 ± 10.8% of the disaccharides, resp., was excreted into the urine. In contrast, after the inj. of ^{14}C-labeled maltose, 54.6 ± 7.0% was oxidized to $^{14}CO_2$ and 4.8 ± 3.9% was excreted in the urine. The per cent of maltose oxidized to CO_2 was similar to that of glucose. In addition to small intesti mucosa, homogenates of rat kidney, liver and brain as well as serum were found to have measurable maltase activities. The role of th tissue maltases in the metabolism of circulati maltose and maltosyloligosaccharides is discus

5761 THE EFFECTS OF ZINC DEFICIENCY ON PANCREATIC CARBOXYPEPTIDASE ACTIVITY AND PROTEIN DIGESTION AND ABSORPTION IN THE RA (E.) Mills, C. F. (Rowett Res. Inst., Bucksbu Aberdeen, Scotland), J. Quarterman, R. B. Will A. C. Dalgarno and B. Panić. Biochem. J. 102(712-718, 1967.

Proteolytic enzyme activities were studied in the pancreas of Zn-deficient and control rats. No change was detected in trypsin-plus-chymotrypsin activity. Carboxypeptidase activity w appreciably lowered in Zn deficiency and rapid returned to normal on Zn therapy. When U-^{14}C-labeled *Chlorella* protein was fed, there was n evidence that reduction in carboxypeptidase activity had limited the rate of protein diges or absorption. Specific activity of pancreati protein synthesized during these experiments w much lower in Zn-deficient rats than in contro A higher proportion of the total activity pres in each organ examined, was in the non-protein fraction in Zn-deficient rats.

5762 RATE OF SPLITTING AND ABSORPTION OF PROTEIN (CASEIN I^{131}) IN THE DIGESTI TRACT AND EXCRETION OF PRODUCTS OF ITS HYDROLY WITH BILE. (Rus.) Zamychkina, K. S. (Inst. Normal Pathol. Physiol., Moscow). Biull. Eksp Biol. Med. 62(11):17-19, 1966.

Healthy dogs and dogs with pathological liver changes, induced by experimental fistula of th gallbladder, were fed with ^{131}I-labeled casein (100-200 cpm/g). The labeled protein was quic hydrolyzed by gastric and intestinal juices, a confirmed by *in vitro* experiments, and the radioactive split products appeared in the blo Their level reached a max. 60-90 min. after admin. of the labeled protein, and were rapidl excreted from the blood of healthy dogs; they accumulated in the bile. In dogs with hepatit the excretion of these split products from the blood and their accumulation in the bile w markedly decreased. Thus, the bile-producing function of the liver plays an essential role the excretion of protein digestion products no utilized by the organism from the blood.

MOTILITY

'63 PROPERTIES OF THE INHIBITORY POTENTIAL
OF SMOOTH MUSCLE AS OBSERVED IN THE
SPONSE TO FIELD STIMULATION OF THE GUINEA-PIG
ENIA COLI. (E.) Bülbring, E. (U. Oxford,
gland) and T. Tomita. J. Physiol. (London)
39(2):299-315, 1967.

ne inhibitory potential evoked by field stimula-
on of the guinea pig taenia coli was studied
n hypertonic soln. in which the spontaneous
lectrical and mechanical activity was slowed or
bolished. No direct correlation was found between
ne inhibitory potential and the muscle membrane
olarization in response to the stimulating
urrent. Chronaxie for the inhibitory potential
as less than 1 millisec.; that for the muscle
pike was 20-30 millisec. The inhibitory potential
ecreased in size along the tissue when one end
f the tissue was stimulated; its spatial decay
as slower than that of the electrotonic potential
n the muscle bundle. Tetrodotoxin (5 x 10^{-7}
/ml) abolished the inhibitory potential without
ffecting the electrical properties of the muscle
embrane. It is suggested that the inhibitory
otential was the result of stimulation of intrin-
ic inhibitory nerves. Properties of the intrinsic
erve fibers derived from these experimental
esults were three-fold: 1) the length of the
erve fibers is probably only a few mm and the
pace constant is of the order of 0.1 mm; 2) no
epetitive firing is produced by a long current
ulse; and 3) the absolute refractory period is
-4 millisec.

764 EFFECTS OF VASODILATORS ON THE ISOLATED
TAENIA COLI OF THE GUINEA-PIG. (E.)
mai, S. (Tokyo Med. & Dent. U., Japan) and
. Takeda. Nature (London) 213(5075):509-510,
967.

uinea pig taenia coli were mounted in a sucrose-
gap apparatus as described by Burnstock and
Straub. Arrangements were made to record isometric
contractions simultaneously with electrical
activity. Nitroglycerine, papaverine hydrochloride,
theophylline ethylenediamine, adenosine and
epinephrine bitartrate all induced qualitatively
similar changes in the membrane potential, i.e.
inhibition of spike discharge and hyperpolariza-
tion, at the same time that they produced relaxa-
tion. The relaxant effect of papaverine and
theophylline ethylenediamine persisted after
complete depolarization by K_2SO_4; the action of
nitroglycerine and adenosine was abolished by
depolarization in a fashion similar to that of
epinephrine. It is suggested that papaverine and
theophylline inhibit the inward movement of Ca
which is believed to be the cause of the tonic
part of K contracture. In contrast, it is
suggested that nitroglycerine, adenosine, and
epinephrine produce a change only in the polarized
membrane, most probably an increase in affinity
towards Ca. The earlier reported relaxation in
depolarized taenia coli by epinephrine was attributed to preservatives present in the commercially available soln. of epinephrine used.

5765 HEMODYNAMICS OF EXPERIMENTAL ACUTE GASTRIC DILATATION. (E.) Engler, H. S. (Talmadge Mem. Hosp., Augusta, Ga.), T. E. Kennedy, L. T. Ellison, J. G. Purvis and W. H. Moretz. Amer. J. Surg. 113(2):194-198, 1967.

In anesthetized, artificially-respired dogs gastric dilatation was produced by air inj. into the stomach through a catheter tied into the esophagus and maintained by ligation of the pylorus. Arterial and venous pressure readings and blood samples were obtained by catheters in the aorta, abdominal inferior vena cava and thoracic inferior vena cava. In each of 23 dogs the av. mean arterial pressure promptly fell after gastric dilatation (50% of control) and remained depressed through the period of dilatation, returning to normal on deflation of the stomach. Abdominal inferior vena cava pressures were elevated during inflation, from a normal 4-5 mm Hg to 20-22 mm Hg. Pressures in the thoracic inferior vena cava and right atrium showed no significant change. In 7 dogs av. cardiac output fell from 1.34 liters/min. to an output of 0.4 liters/min. during dilatation. The av. stroke vol. fell from 6.8 ml/min. to 2.5 ml/min. during dilatation. The av. peripheral resistance was 6.41 before dilatation and rose to 10.6. The data suggest that arterial hypotension accompanying acute gastric dilatation is the result of decreased venous return secondary to mechanical obstruction of the intra-abdominal inferior vena cava, due to external pressure from an acutely distended stomach.

5766 OBSERVATIONS ON INTRAGASTRIC PRESSURE. (E.) Spence, A. A. (Western Infirm., Glasgow, Scotland), D. D. Moir and W. E. I. Finlay. Anaesthesia 22(2):249-256, 1967.

Intragastric pressure was measured in 23 men, 36 children (7 mo.-12 yr. old), 43 nonpregnant women, all for elective surgery under general anesthesia, and 31 pregnant women, at term, for delivery under general anesthesia. Mean intragastric pressure and pressures for the lithotomy, 20° head up, and 20° head down positions in each group were as follows: 1) men: 7.4 cm (H_2O), + 2.2, -1.3 and + 1.6; 2) children: 6.3 cm, + 2.4, -1.7 and + 1.6; 3) nonpregnant women: 7.3 cm, + 2.2, -1.1 and + 2.0; and 4) pregnant women: 13.6 cm, + 5.6, -2.1 and + 3.2. There was no statistically significant difference for any of the first 3 groups for values observed in any 1 position. In pregnant women there was a very large scatter for readings taken in the lithotomy position; 7 of 31 had high absolute values for intragastric pressure when placed in this position: all were greater than 20 cm and one was greater than 60 cm. With 1 exception each of the 7 patients had a special factor that increased abdominal girth beyond the usual value for pregnant women at term (obesity, twin pregnancy or hydramnios). All nonpregnant patients had a mean intragastric pressure of approx. 7 cm which was increased in the lithotomy and head-down positions and decreased in the head-up position; corresponding values for pregnant women were approx. twice those for nonpregnant women. The concept and significance of a critical opening pressure for the cardia is discussed.

5767 VERIFICATION OF THE PHARMACODYNAMIC EFFECTS OF SPARTEINE. INDEFINITE EFFECTS ON INTESTINAL MOVEMENTS IN HUMANS. (It.)

Gaglio, M. (U. Catania, Italy) and F. Marletta. Boll. Soc. Ital. Biol. Sper. 42(14):915-918, 1966.

The effects of the i.v. admin. of sparteine sulfate (0.8-1.2 mg) on small intestine motility were studied in 12 subjects, of whom 3 were normal and 9 had gastritis or chronic gastroduodenitis (4 of 9 with secondary intestinal disturbances). Before treatment, 4 subjects had normal and 8 abnormal initial enterotensiograms. Sparteine had no effect on the 4 subjects with normal initial tracings nor on 5 with hypertensive initial tracings. In 3 patients with chronic gastric disturbances (and hypertensive initial tracings), sparteine-induced sporadic increases in the intraluminal pressure. β-Waves increased from 25-50 mm (H_2O) to 30-70 mm with no change in frequency (approx. 10/min.) but a slight increase in the duration of each single wave (from 5.5 to 6.5 sec.). The above effects began 7-10 min. after inj. and lasted 20-30 min. The author stresses the sporadic and transitory nature of the effects of sparteine and concludes that in no case did the agent induce intraluminal hypotension similar to that observed with ganglionic blocking agents.

5768 MECHANICAL AND BIOELECTRICAL ACTIVITY OF THE STOMACH WALL. (E.)

Papazova, M., K. Boev, K. Milenov and E. Atanassova. Izv. Inst. Fiziol. (Sofiia) 10:15-24, 1966.

Experiments were carried out in conscious dogs by a modification of the inductographic method of Louckes *et al*. and implantation of electrodes along the length of the stomach after the method described by Papazova and Milenov allowing both bioelectric and motor activities to be recorded. Strain gauges similar to those of Jacoby *et al*. were implanted on the stomachs of anesthetized dogs; in some experiments intragastric pressure was also recorded by balloon. Continuous rhythmic contractions of the stomach wall with a frequency of 4-5 min. were observed in fasted dogs. The intensity of the contractions was approx. 1.7 g and corresponding to them were slow polyphase changes of potential in the electrogastromyogram which appeared in the same rhythm. The contractions were blocked by deep narcosis but the potential changes persisted with unchanged rhythm. Groups of spike-potentials following the slow potentials preceded the appearance of high-amplitude contractions (over 2 g). The higher amplitude waves were preceded by a more continuous group of spike potentials of higher frequency and amplitude.

5769 THE EFFECT OF INTEROCEPTIVE STIMULI DIFFERENT DURATION ON THE AFFERENT VAGAL IMPULSATION. (E.)

Varbanova, A. and V. Sokolov. Izv. Inst. Physiol. (Sofiia) 10:2 35, 1966.

Acute experiments were carried out with 35 artificially-respired paralyzed cats. The afferent vagal activity was recorded by an electrode on the distal end of the nerve in th region of the neck. The other vagus nerve was left intact and was prepared for stimulation by placement of a platinum electrode. The stomac was distended by inflation of a balloon introduced p.o. or through a fistula. Both continu (10 min.) and brief (10 sec.) inflations of the stomach with the same pressure produced a simi cycle of changes in afferent vagal activity. A the beginning of the stimulation an inhibition background vagal activity occurred for a short period after which the afferent impulses gradua increased in amplitude and reached their highes values considerably after the termination of th stimulation. Parallel with the increase in amplitude, the frequency of the impulses gradua began to decrease. Having reached a max. ampli vagal activity gradually returned to the background level with "undulatory" phenomena in the process of subsiding. The duration of the cycl of afferent vagal activity increased with the intensity of the stimulation preceding it. The assumption is expressed that the original diste tion of the stomach caused continuous contracti of the smooth muscles which, in turn, causes continuous changes in afferent activity.

5770 THE KINETICS OF ACTION OF ACETYLCHOLI ANTAGONISTS IN SMOOTH MUSCLE. (E.)

Rang, H. P. (U. Oxford, England). Proc. Roy. Soc. [Biol.] 164(996):488-510, 1966.

Two models were proposed to describe the rate-limiting step in recovery of acetylcholine sensitivity in smooth muslce after exposure to atropine or scopolamine: 1) dissociation-limite model, dissociation of drug-receptor complexes; 2) biophase model, diffusion of drug away from the receptors. The theoretical kinetic properti of the 2 models were worked out mathematically with the aid of an analog computer and compared with data collected in experiments carried out on strips of longitudinal muscle of the guinea pig. Contractions were elicited by acetylcholin or 5-methylfurfuryltrimethylammonium or one of several alkyltrimethylammonium bromides prepared (amyl to dodecyl). The kinetic properties of th antagonists applied singly could be explained by either model provided the size of the biophas e a relation to the binding capacity of the ceptors. Interaction of fast- and slow-acting tagonists were accounted for only by the first del. It is concluded that the kinetics of tion of scopolamine and atropine reflect their te of reaction with receptors, and that measurent of antagonist kinetics is a valid guide to ug receptor rate constants. A consequence of e dissociation-limited model, that persistent tagonists would fail to show the classical rallel shift of log-dose effect curves when sted against agonists of low efficacy, was born t experimentally and this effect was used to directly estimate the equilibrium constants of kyltrimethylammonium salts.

71 A BASIC STUDY ON ANASTOMOTIC DISEASE--ACETYLCHOLINE CONTRACTURE OF MUSCLE RIP OF BLIND POUCH. (Jap.) Miyamura, A. apporo Med. Coll., Japan). Sapporo Igaku Zasshi apporo Med. J.) 28(4/5):329-344, 1965.

etylcholine contractions of isolated longitudinal scle strips and histological changes in the testinal pouch wall were studied in dogs. scle strips were placed in a bath soln. conining 25 mM of K ions under 28° C. No difrences were noted in the conc.-response relationips between control and Type 3 blind pouch scle strips. Strips from a Type 2 blind pouch re much more reactive to acetylcholine than ose from controls; Type 1 blind pouch muscle rips were less reactive to acetylcholine than ntrols. Acetylcholine contractions were depennt upon K conc.; when K conc. were increased om 5 to 40 mM, the height of contraction was adually reduced in both control and blind pouch scle strips. Control and Type 3 pouch strips re dependent to the same degree on K conc.; the esponse of Type 2 blind pouch strips to high nc. of K was somewhat weaker than that of ntrols, while Type 1 blind pouch muscle strips d a much greater reduction of acetylcholine ntractions than control strips when high conc. K ions were used. There were more remarkable egenerative changes in Auerbach's nerve cells d in muscle cells according to the following rder: Type 3 <Type 2 <Type 1. The two muscle ayers became thickened during the development the blind pouch.

772 INHIBITION OF GASTROINTESTINAL MOVEMENT BY SYMPATHETIC NERVE STIMULATION: THE ITE OF ACTION. (E.) Gershon, M. D. (U. Oxford, ngland). J. Physiol. (London) 189(2):317-327, 967.

he mechanism of sympathetic nervous inhibition f gastrointestinal movement was studied in guinea igs and rabbits in order to determine if the rimary action of sympathetic nerve stimulation as on ganglia or on the smooth muscle itself. he effect of sympathetic nerve stimulation did ot resemble the effect of ganglionic blockade r that of removing all nervous tone with tetrodotoxin. The same frequency of sympathetic nerve stimulation to the rabbit jejunum, which inhibited myogenic spontaneous activity, blocked excitatory responses to transmural postganglionic cholinergic nerve stimulation and antagonized contractions in response to drugs acting directly on the smooth muscle. The output of acetylcholine was measured as an indicator of postganglionic nervous activity. In contrast to hexamethonium, stimulation of sympathetic nerves at frequencies of stimulation sufficient to relax the muscle did not reduce acetylcholine output. Sympathetic nerves and vagus nerves to the guinea pig stomach were stimulated individually and simultaneously in the presence of hyoscine. The relaxant responses to stimulation of the 2 nerves summated when they were stimulated simultaneously; this indicated that the transganglionic vagal pathway was not blocked. It is concluded that the effect of sympathetic nerve stimulation is due to the direct action of the released norepinephrine on the smooth muscle.

5773 ATROPINE-LIKE PROPERTIES OF HEMICHOLINIUM-3. (E.) Bertolini, A. (U. Modena, Italy), A. Greggia and W. Ferrari. Life Sci. 6(5):537-543, 1967.

In vitro studies were performed with guinea pig ileum, atria, and uterine horns, rabbit ileum and frog rectus muscle using standard organ bath procedures. *In vivo* experiments were performed in cats. Internal pressure was recorded from jejunal loops, arterial pressure from femoral artery and respiration from a trachial transducer. Hemicholinium-3 (HC-3) *in vitro* antagonized reversibly and selectively the action of acetylcholine on the terminal ileum, the uterine horn and the isolated atrium of the guinea pig. It also antagonized the action of acetylcholine on the isolated rabbit ileum, but only slightly depressed the response to acetylcholine of the frog rectus muscle. The antiacetylcholine action of hemicholinium on guinea pig ileum was not prevented by choline. In the anesthetized cat, hemicholinium suppressed the effect of carbacholine on the intestine, but did not modify the effect on arterial blood pressure. These findings appear to support the hypothesis of an affinity of HC-3 for acetylcholine-binding sites not only pre- but also postsynaptically. HC-3 was considered as the most reliable means for biologically distinguishing acetylcholine from bradykinin.

5774 PRELIMINARY NOTE ON THE CONTRIBUTION OF CINEFLUOROGRAPHY AND THE VIDEO RECORDER TO THE STUDY OF THE PHYSIOLOGICAL BEHAVIOR OF THE ANTRAL REGION OF THE STOMACH. (E.) Vicari, F., R. Dornier, P. Gaucher, P. Arnould and F. Heully. Medicamundi 11(4):134-138, 1966.

Using radiological observation with image intensification and videotape recording 25 subjects were studied in order to make a descriptive analysis of the motility of the antral region and the adjoining gastric and duodenal zones. Fasted subjects were given a standard Ba meal at a set time. The Ba meal reached the stomach as an interrupted jet; in 7 of 25 cases some material immediately passed the pylorus. Active movement of the stomach started after a latency of 2-3 min. The waves of contractions allowed 2 zones in the stomach to be recognized, the vertical part (digestive sack) and the horizontal (excretory canal). In the digestive sack regular peristalsis occurred. The excretory canal by contracting at both ends isolated a certain amount of Ba in a systolic action. Occasionally after a systole a stream of Ba passed through the pylorus (usually 7 min. after the meal). Occasionally the Ba passed as a stream. Passage of the meal through the duodenum occurred 1) without slowing or fractionation, 2) occasional stops, for example, at the inferior bend, 3) occasional reflux to a previous segment by a violent contraction. A periodicity was observed in the development of all these movements. Complete emptying occurred on the av. after 140 min.

5775 DIGESTIVE TRANSIT TIME AND OPEN-FIELD BEHAVIOR OF RATS. (E.) Tobach, E. (Amer. Mus. Nat. Hist., New York City), H. S. Berman, P. S. Gold, K. Thomas and R. Haber. Physiol. Behavior 1(2):125-131, 1966.

Wistar-strain male and female rats were fed food pellets similar in size and shape to common rat chow, but containing a 5% conc. of chromic oxide. Boluses were collected at approx. 20 min. intervals to determine the digestive transit time. Digestive transit time was defined as the time between ingestion of the treated food and the initial appearance of a significant conc. of chromic oxide in the animal feces. In comparing the individual transit time before open-field experience, there was no correlation with open-field defecatory behavior. However, open-field experience significantly decreased transit time. A positive correlation between post-cecal length and digestive transit time in the open-field group suggested that the effect of the open-field was to increase mobility and shorten digestive transit time by shortening the pathway. Open-field experience affected both sexes differently; males not placed in the open-field tended to have longer transit time than females. In the group observed in the open-field, the transit time of males tended to become shorter, but female transit time increased, so that the male-female differences in transit time became non-significant. It is suggested that digestive transit time is useful as a dependent variable in studies of stress and emotional behavior.

5776 THE ACTION OF THROMBIN AND OTHER PROTEOLYTIC ENZYMES ON THE SMOOTH MUSCLE OF DIFFERENT ORGANS. (Ger.) Haustein, K. O. (Pharmacol. Inst., Erfurt, Germany) and F. Markwardt. Arch. Int. Pharmacodyn. 163(2):393-402, 1966.

Strips of thoracic aorta and the posterior ven
cava of the rabbit were mounted in 10 ml baths
in continually oxygenated Tyrode soln.; the
recordings were made at a magnification of 12
times. Uteri excised from infant rats 80-100
strips of guinea pig ileum also mounted in 10
baths, the uteri in de Jalon's soln. and the
ileum in Tyrode's, both oxygenated, were also
used to test the effect of thrombin and other
proteolytic enzymes on smooth muscle. Kymogra
records were made at a magnification of 6 time
Altogether, thrombin, prothrombin, hirudinin,
trypsin, α-chymotrypsin, papain, plasmin,
subtilisin, streptokinase, protease inhibitor
(from beef lungs), and bradykinin were the
enzymes tested upon the smooth muscle preparat
described above. A number of other compounds,
among them dibenamine, dihydroergotamine, LSD$_{2}$
and serotonin were used in conjunction with th
enzymes in some tests. Only thrombin and tryp
caused contraction of smooth muscle in the 4
preparations. Thrombin and trypsin potentiate
the action of epinephrine, norepinephrine,
serotonin and bradykinin on smooth muscle.
Contractions of the ileum induced by either of
the 2 enzymes were inhibited by pretreatment o
the muscle strips by antihistamine drugs or by
drugs or agents which liberate histamine from
the muscle tissue. The inactivation of thromb
by warming to 60° for 10 min. or by phosphoryl
tion caused loss of ability to stimulate smoot
muscle. Hirudinin, a thrombin inhibitor, pre-
vented thrombin from causing contraction of sm
muscle but hirudinin did not affect the abilit
of the muscle to respond to other stimuli.
Tryptic action on smooth muscle was affected i
the same way as the activity of thrombin by
heat denaturation, and phosphorylation, the
presence of antihistamines and protease inhibi

5777 MODIFICATIONS OF THE ELECTRICAL ACTI
OF THE SMALL INTESTINE UNDER ELECTRI
STIMULATION. STUDY IN THE RAT. (Fr.)
Rougereau, A. (Fac. Med., Tours, France) and
J. Thouvenot. C.R. Soc. Biol. (Paris) 106(8-9)
1699-1703, 1966.

Transverse electrical stimulation (3-150 sec.)
of the rat duodenum with a positive current
induced partial fusion of the slow waves withou
a modification of periodicity; negative current
induced marked changes in periodicity and
amplitude. In the jejunum, longitudinal stimul
tion caused more marked abnormalities of the
amplitude and frequency of contractions; unlike
the changes induced by transverse stimulation,
these aberrations persisted after stimulation
was stopped. Prolonged stimulation by a negati
current completely disrupted the contractions.
Stimulation of the secretion of some local fact
(serotonin, villikinin, bradykinin) during
longitudinal electrical stimulation is suggeste
as a possible mechanism for the prolonged distu
ances noted.

5778 GASTRODUODENAL REFLEX IN THE RAT. CONDITIONS UNDER WHICH IT APPEARS.

-.) Harichaux, P. (Fac. Med. Pharm., Tours, nce) and J. Moline. C. R. Soc. Biol. (Paris))(8-9):1703-1705, 1966.

rats with duodenal distention (produced by eral methods) 3-8 cm below the pylorus, gastric flow was reduced, but it remained cyclic and complete spasm was sometimes seen. The response peared after a 20-30-sec. lag period and usually rsisted throughout the time of distention. Some sponses were seen only after repeated stimula- on. Under some conditions, when the stimulus s not cyclic, duodenal distention regularized d moderated gastric output, restoring its ythm (5 cycles/min.) and therefore increasing loric tonus. It is concluded that vagotomy the level of the neck preserves the gastro- odenal reflex, as does i.v. atropine or duodenal ction at the level of distention.

79 COMPARATIVE X-RAY AND ANATOMIC STUDIES OF THE CAT SMALL INTESTINE PRETREATED TH PILOCARPINE WITH REGARD TO THE ORIGIN OF E RELIEF PICTURE OF THE MUCOSA. (Ger.) Lenz, H. . Clin. Bonn, Germany) and H. Brünner. Fortschr. ntgenstr. 106(2):261-271, 1967.

ts were fasted 24-48 hr. before experimentation der anesthesia and then were given 100-150 ml Ba gastric intubation; after the jejunum was lled with contrast material, 0.5-1.0 mg/kg of locarpine was inj. i.m. The effects were served by fluoroscopy and X-ray cinematography. e stimulation of the secretory parasympathetic means of pilocarpine causes an edematous infil- ation of the wall with stoppage of intestinal tility. As a rule, a short time after the set of the hypersecretion, the animal dies from e toxic effects of the drug. Postmortem stologic examination was also made. Ten min. ter the i.m. inj. of pilocarpine the distal op of the jejunum showed a narrowing of the men and an uneven folding of the mucosa parallel a transverse section. The outer border of the oximal loop was lightly notched. The inj. of 25 mg/kg of pilocarpine i.m. caused a great crease in tone followed by peristaltic waves. e secretory stimulation caused a hypersecretion th dilution of contrast medium. The movement fluid into the wall of the intestine brought e mobility to a halt. In the phase of akinesis, e cross markings reached their limit. The lief structure was especially well developed the secretion-filled intestine. The mucosa owed broad swollen cross folds separated by ep grooves. These relief structures remained r some time after death; they were not uniform, eing present in thin-walled sections and much less prominent in opened sections. Histologically the swelling of the mucosa and villi and edema of the wall were most striking. The circular muscle or "ring muscle" when contracted is largely responsible for the cross markings, whereas the muscularis mucosae are gathered into the roofs or higher parts of the mucosal folds. The extreme contraction of the intestinal smooth muscle resulting from pilocarpine causes a shortening of the small intestine, throwing the mucosa into folds accentuated by the edematous swelling.

5780 STUDIES ON THE CAFFEINE CONTRACTURE OF RAT INTESTINAL SMOOTH MUSCLE. (Jap.) Sunano, S. (Sapporo Med. Coll., Japan). Sapporo Igaku Zasshi (Sapporo Med. J.) 29(3/4):220-225, 1966.

Caffeine contracture of longitudinal strips of the rat large intestine was studied under conditions where excitation-contraction coupling was intercepted. In sucrose-Ringer's soln., where all NaCl in ordinary Ringer's soln. was substituted with equivalent sucrose, caffeine (6 mM) induced contracture of the muscle, even to a greater degree of tension than that in ordinary Ringer's soln., while mechanical responses of the muscle to electrical stimulations were abolished in the sucrose-Ringer's soln. In lithium chloride-Ringer's soln. (lithium chloride instead of NaCl), the caffeine contracture was observed almost in the same manner as that in ordinary Ringer's soln., but the responses to electrical stimulations were not observed. Both responses to caffeine and electrical stimulation were abolished by the addition of 0.04-0.2 mM of dinitrophenol to ordinary Ringer's soln. In hypertonic NaCl-Ringer's soln. (1.75-2.5 times of ordinary NaCl conc.), both responses disappeared. The same inhibition of both responses was also observed in hypertonic sucrose-Ringer's soln., where 328 mM of sucrose was added to ordinary Ringer's soln.

5781 EFFECT OF SEROTONIN ON THE SMOOTH MUSCLES OF THE CIRCULATORY SYSTEM AND ALIMENTARY TRACT OF RAT AND GUINEA PIG. (E.) Gawęcka, I. (Sch. Med., Warsaw) and W. Kostowski. Acta Physiol. Pol. 17(1):129-137, 1966.

5782 BEHAVIOR OF GASTRIC MOTILITY DURING APPLICATION OF THERMIC STIMULATION TO THE EPIGASTRIC REGION. (ENDOSCOPIC OBSERVATION). (It.) Mazzone, O. (U. Catania, Italy) and A. Blasi. Arch. Ital. Mal. Appar. Dig. 33(2):185-188, 1966.

5783 SUBMICROSCOPIC STRUCTURE OF LIVER CELLS AFTER ALTERATION OF THEIR SECRETORY RATE.

(Ger.) Dvořák, M. (U. Purkyne, Brno, Czechoslovakia) and D. Horky. Z. Zellforsch. 76(4):486-497, 1967.

Mature female rats (180-200 g) were separated into 3 groups; Group 1 (controls, 4 rats, of which 2 received 0.5 ml paraffin oil p.o.); Group 2 (12 rats) received a single dose of a choleretic each; Group 3 (12 rats) received the choleretic for 4 days; in Groups 2 and 3 half the animals also received sodium dehydrocholate in a single 20-mg dose i.m., the other half 1-phenylpentanol in a single 10 mg dose in 0.5 ml paraffin oil, p.o. The animals were killed 90 min. after the last admin. of drug. Under the electron microscope the liver cells of animals which had received single or multiple doses of a choleretic agent showed submicroscopic changes in the cytoplasm; the nuclei showed their usual ultrastructure; the av. nuclear diameter had, however, been enlarged in the experimental animals which has been observed in liver cells when the rate of bile secretion has been increased; no measurements were given. The most evident morphological changes brought about by hypersecretion were observed in the Golgi complex, the lysosomes, and mitochondria. Alterations appeared also in the bile capillaries. Under the electron microscope no changes were seen in the endoplasmic reticulum, ribosomes, and cell inclusions. On the basis of these observations as well as those reported by others, the most active structures in the secretion of bile are the Golgi complex, the lysosomes and mitochondria. It seems possible that bile is extruded through the cell membrane.

5784 EFFECT OF CORTISONE ON ^{131}I-THYROXINE IN LIVER AND BILE.

(E.) Blomstedt, B. (Karolinska Hosp., Stockholm) and J. Einhorn. Acta Radiol. [Ther.] (Stockholm) 4(6):437-445, 1966.

The effect of cortisone (5 mg or 10 mg) on the total amount of thyroxine in the liver, on the excretion of thyroxine with the bile and on the relationship between total thyroxine and the amount conjugated to the glucuronic acid in liver and bile was studied in 48 male Sprague-Dawley white rats. The specific activity of ^{131}I-thyroxine used was 24-48 mc/mg; a dose of radioactivity of 6 μc/100 g rat wt. was admin. as a single i.m. inj. to each rat. The mean total radioactivity in the liver of 10 control rats sacrificed 9 days after ^{131}I-thyroxine admin. was 3322 ± 165.4 cpm and in 10 cortisone-treated rats, 2466 ± 157.2 cpm, a statistically significant difference. The difference was also significant when the radioactivity/g liver tissue was calculated (298 ± 25.9 cpm and 190 ± 10.5 cpm, resp.) and when the liver radioactivity was calculated in relation to the ^{131}I-dose admin. Approx. 16.5% of the radiothyroxine in the liver was bound to glucuronic acid in liver extracts from control rats sacrificed 72 hr. after admin. of ^{131}I-thyroxine; the corresponding value for rats receiving cortisone was 8.6%. The amount of thyroxine glucuronide, in relation to the tota radioactivity detected in the liver, in all pa was less for the cortisone-treated rat than fo the control; this difference was also statisti significant. Cumulative excretion of radioactivity with the bile between control and cortisone groups showed no significant difference Radiothyroxine in bile was conjugated to glucu acid to a much greater extent than that in the liver; approx. 95% of radiothyroxine in the bi in both the cortisone and control rats was cor jugated to glucuronic acid. These findings su gest that large doses of cortisone accelerate thyroxine release from the glucuronic acid in the liver and influence the excretion of thyro to the blood.

5785 THE FIRST TEN DAYS OF LIVER REGENERA TION AFTER RADICAL HEPATECTOMY IN TH DOG.

(Fr.) Mallet-Guy, P. (Edouard Herriot Hosp., Lyon, France) and N. Chanelière. Lyon Chir. 62(6):801-819, 1966.

In the first 6-7 days after 75% hepatectomy in dogs, liver regeneration (measured by liver wt progressed steadily (50% at 3-4 days, 86% at 6-7 days) and liver wt. remained relatively stabilized until day 10. After day 10, howeve changes in liver wt. varied widely (50-120% at about 21 days). Tracer studies with ^{198}Au sho that these differences resulted from shrinkage of the liver parenchyma in some animals, an irregular and sometimes reversible reaction. SG values were above normal in 6 of 7 dogs with s normal liver regeneration; this was the most reliable biochemical index of regeneration. Histological changes during regeneration were typical, but some animals developed steatosis, glycogen deposition and fibrous changes.

5786 RESPONSE OF THE ISOLATED PERFUSED LI TO THE ADDITION OF FATTY ACIDS.

(Fr Vaisler, L. (Inst. Endocr., Bucharest), E. Costiner and E. Dinulesco. Rev. Roum. Endocr. 4(1):31-34, 1967.

In isolated perfused rat liver, free fatty aci were released into the medium after a 60-min. lag, increasing markedly and steadily to 180 m Following the addition of sodium palmitate, fa acid release decreased sharply in the first 30 min. and fell more slowly to 180 min., then increased slightly until 240 min. The initial decrease (90 min.) was interpreted as uptake o free fatty acids by the liver, with an equilib in the next 90 min. and slight release of free fatty acids at 180-240 min. An autoregulatory mechanism to maintain plasma free fatty acid levels is suggested.

37 EFFECT OF MUSCULAR WORK ON BILE FLOW AND COMPOSITION IN THE RAT. (Fr.)

perray, B. and H. Pacheco. C. R. Acad. Sci.
aris) 263(23)(Ser. D):1887-1890, 1966.

le flow, studied in rats immediately after the
d of an exercise period (1 hr./day for 3 wk.)
after a 24-hr. rest period, was increased to
9% and 106% of control values, resp. Cholic
id composition was substantially unchanged,
t chenodeoxycholic acid output and bile content
re increased in rats studied immediately after
ercise (165% and 143% of control values, resp.);
rats studied after 24 hr. of rest, chenodeoxy-
olic acid output was significantly increased
39% of control values), but its content was not
gnificantly changed (124% of control values).
olesterol content was not significantly af-
cted in either group, or cholesterol output
ter 24 hr. of rest, but cholesterol output
mediately after exercise was significantly in-
eased (135% of control values). The increase
liver cholesterol output seemed to be partially
mpensated by an increase in biliary cholesterol
vels; it was directly related to the amount of
rk done but also seemed to be an indirect, par-
al consequence of food intake in the animals
ter exercise (although all animals were studied
ter a 24-hr. fast).

788 COMPARATIVE STUDY OF FREE AMINO ACIDS IN THE SERUM AND BILE IN LIVER DISEASES
METHOD OF EXAMINATION OF AMINO ACID METABOLISM).

Fr.) Popesco, A. (Inst. Med. Pharm., Cluj,
umania), G. Benga, D. Coman and V. Pop. Rev.
nt. Hepat. 16(8):1419-1428, 1966.

n normal human bile (10 subjects), lysine, serine,
spartic acid, asparagine, threonine, glycine,
eucine, and isoleucine levels were above serum
alues; arginine and histidine were lower, while
ystine, proline, tyrosine, tryptophan and meth-
onine were sometimes present. No quantitative
hanges in serum or biliary amino acids were seen
n patients with biliary dyskinesia (8) or healed
cute infectious hepatitis (4). In active chronic
epatitis (5 cases), serum cystine, lysine,
rginine, and histidine rose; serum valine de-
reased; in the bile, valine increased and cystine
as absent, while lysine, arginine and histidine
decreased. In evolutive chronic hepatitis (5
cases), serum phenylalanine sometimes increased
and biliary amino acids (lysine, arginine, his-
tidine, serine, phenylalanine, leucine, glycine,
valine) increased. In liver cirrhosis (7 cases),
serum tyrosine and phenylalanine rose; in the
bile, alanine and leucine rose, while lysine,
threonine, glycine and phenylalanine fell. In
hepatic steatosis with obstructive jaundice (3
cases), biliary lysine, histidine, glycine,
valine, aspartic acid, glutamine and isoleucine
disappeared, but no significant changes were noted
in serum amino acids. In porphyria cutanea tarda
(8 cases), serum lysine, alanine, phenylalanine,
isoleucine, leucine, proline and hydroxyproline
rose; in the bile, lysine, alanine, isoleucine,
proline and hydroxyproline were increased, while phenylalanine fell. Biliary amino acid levels differed according to the source of the bile.

5789 EFFECT OF OXYTOCIN ON VARIATIONS OF GLUCOSE AND FREE FATTY ACIDS. STUDY IN ISOLATED PERFUSED LIVER IN VITRO. (Fr.)

Milcou, S. M. (Inst. Endocrinol., Acad. RPR, Bucharest, Rumania), L. Vaisler and E. Costiner. Rev. Int. Hepat. 16(8):1369-1375, 1966.

During 180 min. of incubation, glucose levels in the medium progressively decreased (by about 50%) and free fatty acids increased (by about 100%, especially in the last 90 min.). In rat liver preparations treated with oxytocin (500 mU) after 90 min. of incubation, glucose levels in the medium rose about 15% within 10 min., remained at this level for 30 min., then fell to control levels by the end of the study. Free fatty acid levels remained stationary for the first 30 min. after treatment, then rose (more slowly than in control preparations) in the next 30 min., then fell from 150-180 min. of incubation. A direct action of glycogen on hepatic glycogen is suggested.

5790 THE UPTAKE OF FIBRIN AND FIBRIN-DEGRADATION PRODUCTS BY THE ISOLATED PERFUSED RAT LIVER. (E.)

Gans, H. (U. Minnesota Sch. Med., Minneapolis) and J. T. Lowman. Blood 29(4):526-539, 1967.

The uptake of ^{75}Se-labeled rat fibrin and a specific preparation of fibrin degradation products by an isolated, perfused liver was investigated. The rapid phase $t^{1/2}$ for fibrin in the perfusate was approx. 9 min.; this was comparable to that found for aggregated ^{131}I bovine serum albumin and colloidal Au in the same system. Loss of activity from the blood closely paralleled the increased activity recorded in the liver. No radioactivity was found in the bile samples or the trichloroacetic acid-soluble fraction of plasma. Microradioautographs of washed liver tissue after the labeled, fibrin perfusion suggested the presence of the label on or in the Kupffer cells. Labeled rat fibrin preparations, digested by the action of "cold" rat plasmin to a distinct endpoint, contained 3 distinct fractions on paper electrophoresis. Addition of these fractions to the perfusate resulted in approx. 25% clearance of radioactivity over a 3-hr. period. Thus, clearance of this specific fibrin degradation product preparation occurred at a much slower rate than that of fibrin; the $t^{1/2}$ was in excess of 12 hr. These results apparently confirm Lee's observation that cells of the reticuloendothelial system are involved in the elimination of free circulating fibrin and its metabolic products.

5791 THE EFFECT OF AMMONIUM CHLORIDE ON THE RNA CONTENT OF THE RAT LIVER. (E.)

Basch, A. (Univ. Med. Sch., Szeged, Hungary) and F. Joó. Acta Med. Acad. Sci. Hung. 23(1):7-13, 1966.

Inbred male albino rats were given ammonium chloride (NH_4Cl; 0.1 g) every second day over a period of 20 days. Subsequent histochemical staining showed increased pyroninophilia, while electron microscopy demonstrated an enriched ergastoplasm in the liver cells. Both findings suggested an increased RNA content in the liver, which was quantitatively measured as a 24.8% increase. The data suggest that NH_4Cl treatment led to increased intrahepatic protein synthesis.

5792 REGENERATION OF THE MAMMALIAN LIVER. V. MITOTIC DIVISION IN CYTOLOGICALLY DIFFERENTIATED LIVER CELLS.

(E.) Lane, B. P. (New York U. Sch. Med., N. Y.) and F. F. Becker. Amer. J. Path. 50(3):435-445, 1967.

After a 70% hepatectomy in the rat (male albino Sprague-Dawley), residual liver tissue entered a period of cell division which resulted in replacement of the excised liver mass. During the early period after surgery, hepatocytes underwent extensive morphologic simplification of both surface structures and cytoplasm. Normal structural components were reconstituted very rapidly between the ninth and fourteenth postoperative hr. This restoration resulted in a cell almost identical to an unstimulated hepatocyte, even though nucleic acid synthesis and the subsequent steps in preparation and participation in mitotic division were occurring. However, transient cytoplasmic degradation was detected at the time of DNA synthesis and was again followed rapidly by total cytoplasmic reconstruction. The presence of lysosomes in the perinuclear area during cytokinesis was confirmed.

5793 THE EFFECT OF CHOLECYSTOKININ-PANCREOZYMIN PREPARATIONS ON HEPATIC BILE OUTPUT IN FASTING AND DIGESTING DOGS.

(E.) Jonson, G. (Karolinska Hosp., Stockholm, Sweden), G. Svartengren and L. Thulin. Acta Physiol. Scand. 69(1-2):23-28, 1967.

Three adult mongrel dogs were cholecystectomized and provided with a permanent external 2-part common duct fistula. The output of hepatic bile during infusion of cholecystokinin-pancreozymin preparations was studied during fasting, during digestion of food with bile and during infusion of dehydrocholic acid. Biological activity of all the preparations was approx. 200 Ivy dog U of cholecystokinin, 800 Crick, Harper and Raper U of pancreozymin and 10-12 clinical U of secretin/mg; with infusions, the secretin dose never exceeded 1 clinical U/kg body wt. and hr. (below the threshold for choleretic effect). In the fasting state with no infusion the bile output was equal to initial values; infusion during fasting doubled bile output. During digestion with no infusion, bile output was increased 3-4 times over initial values. Infusion during digestion gave either a decrease of output or an initial increase followed by a decrease. During fasting with dehydrocholic acid infusion, bile output was 6 times greater than initial values, and with superimposed hor monal infusion, output was increased further b approx. 15%. These patterns appeared to be re lated to the gastric and duodenal activity dur the experiments. It is concluded that physiologic or pharmacologic interventions on hepati bile output should be evaluated only when side effects on gastrointestinal motility and secre tion can be excluded.

5794 THE DISTRIBUTION OF BILE SALTS ALONG THE SMALL INTESTINE OF RATS.

(E.) Eastwood, M. A. (Roy. Infirm., Edinburgh, Scotland) and G. S. Boyd. Biochim. Biophys. A 137(2):393-396, 1967.

Wistar rats were fed a low-bulk stock diet (70 wholemeal flour, 25% skimmed milk powder and 5 brewer's yeast) and water freely. Alterations of this diet included substitutions of 10% cellulose (5 rats, 2 experiments); 25% cellulose (3 rats, 1 experiment); 10% sodium carboxymethy cellulose (3 rats, 1 experiment) and all regime were maintained for at least 10 days prior to sacrifice. The effects of the various regimens on the dihydroxy and trihydroxy bile acid conte were measured. Rats were opened by abdominal approach and the small intestine clamped at the ileocecal valve prior to dividing the small intestine into 4 equal parts. Contents from ea intestinal segment were freely drained into centrifuge tubes and centrifuged for 45 min. at 2600 x g. Animals on a stock diet only showed a biphasic distribution of a pellet [solid component] and supernatant both of which increased quantitatively along the intestine per each quarter segment. Rats fed carboxymethyl-cellul and cellulose showed increases in the pellet an supernatant phases, resp. A progressive increa in trihydroxy acid conc. in the first 3 quarter and a substantial decrease in its conc. in the fourth quarter was observed in rats fed a stock diet. The same results were obtained for all other diets, except 25% sodium carboxymethylcellulose. A similar decrease between the thir and fourth quarters was noted for dihydroxy aci conc. in rats fed a stock diet except that it was limited to the supernatant phase. In rats fed other regimens, a uniform decrease in dihydroxy acid conc. was obtained along the length the small intestine. It is concluded that intestinal bile salts are partitioned between non absorbable bulk and the aqueous phase and are closely related to the water content of the intestinal segment. An increase in polysaccharid in the diet (as in cellulose-fed rats) results in an increased bile salt content of the small intestine (supernatant phase).

5795 BINDING OF SULFOBROMOPHTHALEIN SODIUM (BSP) AND OTHER ORGANIC ANIONS BY ISOLATED HEPATIC CELL PLASMA MEMBRANES IN VITRO.

(E.) Cornelius, C. E. (Kansas State U., Manhattan), J. Ben-Ezzer and I. M. Arias. Proc. Soc. Exp. Biol. Med. 124(2):665-667, 1967.

lated, hepatic cell plasma membranes (rat)
nd, on the av., 160 ± 2 µg BSP/mg of membrane
tein and 1.4 ± 0.1 µg BSP/U of Co^{+2}-cytidine
ophosphatase activity. BSP binding was con-
nt between pH 7-8, but increased binding oc-
red at lower pH's. BSP binding was max. at
µg BSP/ml in the incubation mix, while pro-
tionately less binding was seen at lower conc.;
conc. above 500 µg/ml reduced BSP binding and
sed dissolution of cell membranes. Max. BSP
ding was complete by 3 min. and did not in-
ase on incubation up to 120 min. Addition or
stitution of Ca, Mg, K and Cl ions to the
ffer system at 0.05 M did not enhance BSP
ding; however, binding was greatly depressed
substitution of distilled H$_2$O for the Na$_3$PO$_4$
ffer. Fluorescein, taurocholate and bilirubin,
ich do not compete for hepatic uptake with BSP
en inj. simultaneously in vivo, had little or
interference with BSP binding by hepatic cell
asma membranes in vitro. Other organic ions,
ch as indocyanine green, flavaspidic acid gluc-
inate and iodipamide methyl glucamine, which
mpete with BSP for hepatic uptake in vivo, sig-
ficantly reduced BSP binding by isolated mem-
anes in vitro; the av. per cent interference with
P binding by these 3 agents was 51%, 64% and
%, resp.

96 INFLUENCE OF PROTRACTED INFUSION OF
GLUCOSE AND INSULIN ON THE COMPOSITION
D REGENERATION ACTIVITY OF LIVER AFTER PARTIAL
PATECTOMY IN RATS. (E.) Šimek, J. (Charles U.,
adec Kralove, Czechoslovakia), V. Chmelař, J.
lka, J. Pazderka and Z. Charvat. Nature (London)
3(5079):910-911, 1967.

le rats were subjected to partial hepatectomy
esection of 65-70% of the liver) and then
vided into 4 groups. Group 1 included normal
ts in which the rest of the liver remaining
fter partial hepatectomy was analyzed. Rats in
oup 2 were given an infusion of Ringer's soln.,
ts in Group 3 were given 20% glucose (in Ringer's
ln.) and in Group 4, they were given 20% glu-
se containing 0.02 I.U. of crystalline insulin/ml.
nfusion was done for 5 min. each hr. at a dose of
.3 ml/100 g body wt. Two hr. before sacrifice,
ritiated thymidine (200 mc/0.4 ml/200 g) with a
pecific activity of 6.0 c/mmole was inj. The
ncorporation of thymidine-^{3}H into liver cell
uclei was monitored, and the mitotic index
number of mitoses found in 10^{3} nuclei of paren-
hymal liver cells) was ascertained. Thirty-four
r. after partial hepatectomy there was a smaller
ncrease in the wt. of liver that remained after
esection, and also a smaller total amount of
ipids, protein nitrogen, RNA and DNA in the
iver tissue of rats which received insulin and
lucose than in those of the other experimental
roups. In addition, values of the mitotic index
ere considerably lower and the number of nuclei
f parenchymal liver cells labeled with thymidine-
H were decreased in rats that received both in-
ulin and glucose. Insulin admin. with glucose
ncreases lipogenesis, especially in the adipose tissue, and at the same time inhibits the liberation of free fatty acids from this tissue. Slackening of the growth of the lipid content in the liver probably is connected with the limited mobilization of free fatty acids from the fat deposits which usually occur after partial hepatectomy. It is thought that as a consequence of the partial inhibition of the growth of lipids in the liver, a shift of liver metabolism occurs, and that the decrease in the regenerating activity of the liver which was observed is probably related to the inhibited development of these changes.

5797 CATABOLISM OF TRYPTOPHAN BY THE ISOLATED, PERFUSED LIVER AND INTESTINE. (E.) Altman, K. I. (Euratom, Mol, Belgium) and G. B. Gerber. Nature (London) 213(5079):911-913, 1967.

The catabolism of tryptophan by the isolated, perfused liver and intestine of the rat was studied using a perfusion fluid of 40 ml of fresh, heparinized rat blood diluted with a third of its vol. of Ringer's soln. and containing 200 mg of glucose. Tritiated L-tryptophan and DL-tryptophan (indolyl-2-^{14}C) labeled with ^{14}C were used in all experiments. Animals were fed a standard diet that contained all of the important vitamins, including 6.5 mg/kg of pyridoxine, and they were starved for 18 hr. before perfusion. Perfusions were done either at physiological conc. of tryptophan (4 µmoles) or in conditions of tryptophan loading after addition of 50 µmoles of L-tryptophan to the perfusion medium. In the liver catabolism of tryptophan occurred rapidly, primarily by way of the kynurenine pathway, resulting in formation of compounds devoid of ^{14}C. Substantial quantities of tryptophan metabolites were excreted into the bile, but some of these were devoid of ^{14}C and contained only tritium; 1 of the main products of excretions in the bile was tentatively identified as 3-hydroxyanthranilic acid. Initially tryptophan disappeared more slowly in conditions of tryptophan loading, but its catabolism increased as the perfusion progressed, possibly due to induction or activation of tryptophan pyrrolase after addition of 50 µmoles of L-tryptophan. Approx. 20-30% of total activity of ^{14}C was present in protein-bound serine and alanine after 2 hr. of perfusion. Tryptophan catabolism by the kynurenine pathway was very small in the intestine; in contrast to liver, there was no loss of ^{14}C and no detectable formation of tritium oxide. However, the formation of at least 1 tryptophan metabolite, tentatively identified as indole acetic acid, was noted.

5798 RELEASE OF AN ESTERASE FROM LIVER UPON HEPARIN INJECTION. (E.) De Meis, L. (U. Brazil, Rio de Janeiro) and R. Maroja. Quart. J. Exp. Physiol. 52(2):174-183, 1967.

Heparin induces the release of an esterase from liver. Several organs were perfused with in vitro heparinized blood (500-800 I.U. per cent), and esterase activity was measured manometrically in a Warburg apparatus. Postheparin esterase was differentiated from the pseudocholinesterase normally found in plasma by its resistance to prostigmine. Clearing-factor activity was measured by the decrease of plasma turbidity in the presence of dog chyle. Attempts were made to differentiate post-heparin esterase from the clearing factor. Heart-lung and hind limb perfusions with *in vitro* heparinized blood caused release of clearing factor into the perfusion medium, but no postheparin esterase activity was found. Liver perfusion with *in vitro* heparinized blood released both clearing factor and esterase; max. esterase activity was obtained after 2-4 min. of perfusion. The presence of heparin was required for the release of esterase, since perfusion with citrated blood did not release the enzyme. Perfusion of liver with a suspension of RBC in saline-glucose-heparin soln. released postheparin esterase, but no clearing factor activity was found. Perfusion with a similar mixture without heparin did not release the esterase. Extracts of heart powder with *in vitro* heparinized plasma exhibited only clearing factor activity. Postheparin esterase was strongly inhibited by protamine sulfate and was capable of hydrolyzing several low molecular wt. esters.

5799 COPPER CONTENT AND DISTRIBUTION IN SUBCELLULAR FRACTIONS OF LIVER FROM NORMAL AND COPPER SULPHATE TREATED RATS. (E.)

Roussanov, E. and P. Balevska. *Izv. Inst. Fiziol. (Sofiia)* 10:163-169, 1966.

Male albino rats (40) were divided into a control group (19) and an experimental group (21); the latter received a diet of bread, milk and oats supplemented over a 90-day period with 10 mg of Cu/day in the form of copper sulfate. In controls, the total Cu conc. of the liver was 4.7 ± 0.25 μg Cu/g fresh tissue; it was distributed among the cellular fractions as follows: mitochondria, 0.15 ± 0.013; nuclei; 0.26 ± 0.04; microsomes, 0.17 ± 0.024; and hyaloplasm, 0.43 ± 0.036 μg/mg of N. Under identical conditions of treatment, the experimental animals fell into 2 subgroups. In Subgroup 1, there was an approx. 14-fold increase in Cu content in the liver (70.1 ± 8.7 μg Cu/g fresh tissue). The bulk of the Cu was deposited in the mitochondria (3.5 ± 0.46 μg/mg N); in other cellular fractions it was as follows: nuclei, 1.2 ± 0.27; microsomes, 0.49 ± 0.10 and hyaloplasm, 1.5 ± 0.19 μg/mg N. In Subgroup 2, there was a 100-fold increase in liver Cu content (572.6 ± 50.5 μg/g fresh tissue); most was deposited in the nuclei (69.4 ± 19.9 μg/mg N), while other cellular fractions were as follows: mitochondria, 20.8 ± 1.9; microsomes, 4.8 ± 0.43 and hyaloplasm, 13.9 ± 1.8 μg/mg N. In Subgroup 2, there was a statistically significant increase in the RNA/DNA ratio (2.65 compared to 2.22 in Subgroup 1). These findings indicate 2 different mechanisms of Cu metabolism in the liver.

5800 QUANTITATIVE MICROANALYSIS OF BILE.

(E.) Nakayama, F. (Kyushu U. Fac. Me Fukuoka, Japan). *J. Lab. Clin. Med.* 69(4):594-609, 1967.

A quantitative microanalytical procedure for bi was developed which is based on the solvent par tition of bile constituents into subgroups followed by silicic acid column chromatography, ga chromatography and thin-layer chromatography. This method can be performed with less than 1 m of bile and can readily be scaled down to be applicable for experimentation on smaller anima It gives information on a wide variety of const uents present in bile, including total phospholipids; lecithin; and its fatty acid compositio cholic, chenodeoxycholic, deoxycholic and litho cholic acids; free fatty acids; cholesterol; mono-, di- and triglycerides; bilirubin; total solid; and total lipids. The quantitative anal sis of human gallbladder bile is presented.

5801 THE REGULATION OF INSULIN SECRETION: EFFECTS OF THE INFUSION OF GLUCOSE, RIBOSE, AND OTHER SUGARS INTO THE PORTAL VEINS OF DOGS. (E.)

Goetz, F. C. (U. Minnesota Sch. Med., Minneapolis), J. W. Maney and B. Z. Greenberg. *J. Lab. Clin. Med.* 69(4):537-557, 1967.

Small amounts of the following monosaccharides were infused into the portal veins of anestheti dogs in acute experiments: D-ribose, D-galacto D-fructose, D-glucose and D-2-deoxyglucose; thi was done to study the possibility of existence a regulator of insulin secretion outside of the pancreas itself. Insulin was measured by immun assay in pancreatic venous blood, and the parti min. output of insulin was noted. Ribose, glucose and galactose caused increases in the secretion rate of insulin, in the absence of a rise in arterial glucose conc. A questionable rise in insulin output was noted during and aft infusion of D-2-deoxyglucose, again without a rise in arterial glucose conc. These results and those of others support the existence of a carbohydrate-sensitive regulator of insulin sec tion outside of the pancreas; they do not indicate its location with certainty, but it is suggested that the liver is a possible site of such a receptor.

5802 EFFECTS OF PORTACAVAL SHUNTS ON FLOW AND COMPOSITION OF BILE. (E.)

Neistadt, A. (U. Rochester Sch. Med. & Dent., N. Y.), J. F. C. Lima and S. I. Schwartz. *Surge* 61(3):427-431, 1967.

After side-to-side and end-to-side portacaval shunts in dogs, no alterations were observed in the hourly bile flow under basal conditions. Bile composition was not altered by the acute shunting procedure; however, bile was conc. in dogs with chronic shunts. The hepatic arterial flow increased temporarily after the shunt, but decreased to below preshunt values in animals studied at 3 wk. The liver with a chronic shunt showed less response to a hydrocholeretic when compared with that of the control. No significant difference in choleretic response, bile flow and hepatic arterial flow was observed when side-to-side and end-to-side shunts were compared.

5803 RELEASE OF ENZYMES FROM THE LIVER. (E.) Schmidt, E. (Med. Clin., Hanover, Germany) and F. W. Schmidt. Nature (London) 213(5081):1125-1126, 1967.

The release of cellular enzymes (17) in isolated perfused rat liver was studied. The cell-free perfusion medium (a physiological saline soln. containing 25 g bovine albumin, 5.2 mmoles glucose, 1.3 mmoles lactate and 0.1 mmoles pyruvate/liter^2) was saturated with O_2; pH was adjusted to 7.30 and shifted during perfusion to 7.14. The perfusion medium temperature immediately before its entrance into the portal vein was 37°C; flow rate was 1-3 ml/g-liver/min. Omission of RBC from the perfusate caused a definite hypoxic lesion of liver cells with a decreased consumption of O_2. Av. loss of soluble protein from the liver was 30%. Within 4 hr. of perfusion, there was a remarkable increase in enzyme activity in the circulating medium. The enzyme pattern was split into 3 groups, the activities of which differed from each other by approx. an order of magnitude. Rates of release of most enzymes followed their resp. conc. gradients between liver and circulation system (enzymes with high activities in the liver cell reached high conc. in the extracellular space, while those with low activities in the cell did not reach high conc.). Rate of release was also inversely proportional to their resp. molecular wt.: the higher the molecular wt., the lower the percentage of intracellular activity found in the perfusion medium. Three enzymes did not follow this rule: glutamate dehydrogenase, glutamic-oxalacetic transaminase and malic dehydrogenase. This indicated that the intracellular distribution delayed release from the cells; glutamate dehydrogenase is solely in the rat liver cell mitochondria, which also contains more than 70% of the glutamic-oxalacetic transaminase and 40% of the malic dehydrogenase. The other enzymes studied originate from the cellular cytoplasm. Most of the activities of malic dehydrogenase and glutamic-oxalacetic transaminase found in the perfusion medium were derived from their cytoplasmic isoenzymes, which behaved like the other cytoplasmic enzymes, depending on their conc. gradient and their molecular wt. However, conc. of the mitochondrial isoenzymes, and the glutamate dehydrogenase, did not exhibit this correlation.

5804 EFFECTS OF THE ADMINISTRATION OF SOMATOTROPIC HORMONE ON HEPATIC AND SERUM PROTEINS. (It.) Cascone, O. (U. Catania, Italy) and F. Marletta. Boll. Soc. Ital. Biol. Sper. 42(14):911-914, 1966.

Serum and hepatic protein levels were determined in 21 rats (11 male and 10 female; age 2 mo.) following the i.m. admin. of somatotropic hormone (2 Evans U/day) for 24 (Group 1), 28 (Group 2), or 33 (Group 3) days. Wt. gain was negligible in rats treated for short periods and moderate (+16% compared to controls) in those treated for longer periods. The liver/somatic wt. ratio was decreased only in animals of Group 1. Hepatic nonprotein nitrogen levels increased in animals of Group 1, but were unchanged in those of Groups 2 and 3. Hepatic total protein levels were decreased only in animals of Group 1. Hepatic protein determination revealed an increase in albumin and the slow-migrating globulins but a decrease in the intermediate globulins (α_2-β). It is concluded that somatotropic hormone in the early stages of treatment does not cause a noticeable anabolic effect in the liver, whereas prolonged treatment causes an anabolic effect in the liver parallel to the increase in body wt.

5805 THE RELATIONSHIP BETWEEN LIVER AND PINEAL BODY. MORPHOLOGICAL AND HISTOENZYMATIC STUDIES IN THE EPIPHYSECTOMIZED RAT. (It.) Barbanti Silva, C. (U. Modena, Italy), G. P. Trentini and G. Barbolini. Arch. De Vecchi Anat. Pat. 46(1):65-97, 1965.

Morphological, histological and enzyme studies were conducted in the livers of 30 female Wistar rats (140-160 g) 70 days after incision of the superior longitudinal sinus alone (15 controls; Group 1) or after epiphysectomy according to the Thieblot-Le Bars technic (15 rats; Group 2). In animals of Group 2, morphological changes in the liver consisted of loss of laminar structure; reduced basophilia of the cytoplasm, cloudy and vacuolar degeneration, and beginnings of fatty degeneration of hepatocytes; irregular form and vol. of the Kupffer cells; thickening and irregular appearance of the reticular network (Mallory stain); increase in the number of collagenous fibers (Gomori stain) in the portal spaces and distribution around the hepatic vein. The hemosiderin content of the Kupffer cells (as determined by the Perls Prussian blue test) in rats of Group 2 was very low, i.e. similar to that observed in animals of Group 1. The activity of the following enzymes in the Kupffer cells of rats of Group 2 were either unchanged or decreased with respect to that of Group 1: alkaline and acid phosphatase (Burstone method); succinic dehydrogenase, TPN-diaphorase, DPN-diaphorase, glucose-6-phosphate dehydrogenase, and glutamic dehydrogenase (Balogh-Cohen method). It is concluded that epiphysectomy causes neither evident siderosis in the Kupffer cells of the liver (contrary to the intense siderosis observed in the histiocytes and follicles of the spleen following epiphysectomy in previous studies by the authors) nor increase in enzyme activity.

5806 THE INFLUENCE OF CONJUGATION OF CHOLIC ACID ON ITS UPTAKE AND SECRETION:

HEPATIC EXTRACTION OF TAUROCHOLATE AND CHOLATE IN THE DOG. (E.) O'Máille, E. R. L. (U. Liverpool, England), T. G. Richards and A. H. Short. J. Physiol. (London) 189(2):337-350, 1967.

Sodium taurocholate or cholate was systemically admin. at constant rate of approx. 2.9 μmole/min./kg body wt. to anesthetized dogs in which the common bile duct had been cannulated. Blood was sampled from systemic and hepatic veins under steady-state conditions, and the fraction of bile salt removed in a single passage through the liver was determined. Total hepatic blood flow was estimated by use of the Fick principle. The hepatic extraction fraction for synthetic taurocholate in 10 experiments was 92% ± 5% over the blood flow range encountered (1.1-2.8 ml/min./g-liver). Extraction of cholate extensively conjugated in the liver before excretion into bile was 79% ± 8%. Under circumstances of similar hepatic blood flow, extraction of cholate transferred to bile in the free form (after acute taurine depletion) was significantly less than that of either synthetic taurocholate or cholate which could be actively conjugated before excretion. These findings support previous studies on the advantage of conjugation in the transfer of cholic acid from blood to bile. The hepatic clearance of bile salt decreases with an increasing rate of admin., but the values obtained may be influenced by changes in hepatic blood flow. An increase in total hepatic flow was observed when the admin. rate of taurocholate exceeded approx. 5 μmole/min./kg body wt. The secretory max. for glycocholate, a bile salt not normally found in canine bile, was of the same order as that for taurocholate.

5807 POOL SIZE AND TURNOVER OF BILE ACIDS IN SIX HYPERCHOLESTEREMIC PATIENTS WITH AND WITHOUT ADMINISTRATION OF NICOTINIC ACID. (E.) Wollenweber, J. (Mayo Clin., Rochester, Minn.), B. A. Kottke and C. A. Owen, Jr. J. Lab. Clin. Med. 69(4):584-593, 1967.

Turnover, biological half-life and pool size of chenodeoxycholic and cholic acids were simultaneously determined in 6 hypercholesteremic patients by the admin. of ^{14}C-labeled cholic acid and tritium-labeled chenodeoxycholic acid, and by following the rate of disappearance of radioactivity from the bile. In 9 of 10 determinations the half-life of chenodeoxycholic acid was somewhat longer and its turnover was smaller than that for cholic acid. The hypocholesteremic effect of nicotinic acid in the 6 patients was accompanied by alterations of bile acid metabolism, but they did not follow any consistent pattern. In spite of considerable variations in some parameters of cholic and chenodeoxycholic acid metabolism, the combined turnover of both bile acids was not altered significantly by admin. of nicotinic acid.

5808 ANTIGENIC PROPERTIES OF LIVER CELL NUCLEI OF RATS OF DIFFERENT AGES. (Uk.) Zaichenko, A. P. (Acad. Med. Sci., Kiev, USSR). Fiziol. Zh. (Kiev) 13(2):262-266, 1967.

41 INFANTILE GASTROENTERITIS. STUDIES OF
A POSSIBLE VIRAL ETIOLOGY. (Fr.)
ylet, R. (Fac. Med., Dakar, Senegal), S. Dauchy
d A. B. Maffre. Bull. Soc. Path. Exot. 59(2):
3-187, 1966.

teroviruses were isolated from 59 of 387
ildren under 4 (15.2%) with epidemic diarrhea;
e incidence in 1961, 1963 and 1964 was 28%,
% and 9.6%, resp. In 375 control children, the
cidence in the same periods was 18%, 12.96%
d 6.5%, resp. (total 14%). In the children
th diarrhea, virus types included ECHO in
2%, polio in 3.6% and Coxsackie in 3.6%. ECHO
ruses were encountered more frequently in the
ntrol group (8.15%); the other 2 virus types
re not consistently or significantly more
equent in the children with gastroenteritis.
her virus types (adeno, herpes, influenza,
patitis) also appeared to be non-significant.
is concluded that enteroviruses play a
gligible part in the etiology of diarrhea in
negalese children.

42 ROUTINE RECTAL SWAB CULTURE. AN
EPIDEMIOLOGICAL SURVEY IN THE ELDERLY.
.) Mechie, A. M. (Foresthall Hosp., Glasgow,
otland) and J. G. Pritchard. Practitioner
8(1185):396-401, 1967.

a survey of 1,529 patients over 60 yr. old on
om culture of rectal swabs was done at
spital admission, there was a 3.9% incidence
intestinal infection, chiefly Shigella and
cherichia. Such individuals may be a potential
urce of infection to young children in a 3-
4-generation household. It is thought that
infection rate among geriatric admissions of
in 25 cases justifies the laboratory time
pended on routine rectal swab culture.

343 PRINCIPLES OF GENERAL AND ANTIBIOTIC
TREATMENT OF GASTROENTERITIS CAUSED
E. coli. (Fr.) Gyergyai, K. (Istvan Apathy
ildren's Hosp., Budapest) and G. Páll. Ann.
aediat. 207(5):307-320, 1966.

f 1181 infants and children with E. coli
nteritis, 170 (14.4%) were asymptomatic
arriers, 477 (47.2%) had slight symptoms, 386
38.2%) had moderate symptoms, 122 (12.1%) had
evere disease and 26 (2.5%) had toxic disease;
05 of these patients (68.1%) were infants
age 0-9 mo.) and only 6.4% (51) were asymptomatic
arriers. Antibiotics (chloramphenicol deriva-
ives, tetracycline, neomycin, polymyxin B,
ycloserine, colimycin, kanamycin and combina-
ions of these agents) were admin. to 848
ymptomatic patients and 47 asymptomatic
arriers (75.8% of the group). The development
f resistance in the organism was shown by the
ncrease in the number of children who remained
symptomatic carriers (35% of 378 patients
treated in 1957-1960; 50.3% of 517 children treated in 1961-1963). However, only 6 children died (0.59%). Addition of blood transfusions and plasma γ-globulin to a bykomycin-polymyxin B regimen reduced the number of carriers in infants (24.2% of 66 children in 1957-1960, 27.8% of 97 children in 1961-1963). Tetracyclines, chloramphenicol derivatives and cycloserine D were usually unsatisfactory; neomycin and colimycin were effective at first, but after 2-3 yr. of use the bacteria became resistant.

5844 A MODIFIED BIOPSY NEEDLE. (E.)
Wichelman, D. F. (3022 E. 14th St., Oakland, Calif.). Arch. Surg. (Chicago) 94(3): 432, 1967.

A new modified biopsy needle is described which combines the best features of the Silverman needle and the Franklin modification of the latter. The Franklin modification, which uses 2 coapting silver solder plugs at the blade tips, is readily converted to the new needle by removal of one of the silver solder plugs. This new needle has been used for biopsy of the kidney, prostate and liver; tissue yield has been very high and the specimens have often been of exceptional quality. The technic of use of this needle is described.

5845 EXPERIMENTAL EVALUATION OF A CROSS-LINKED GELATIN ADHESIVE IN GASTROINTESTINAL SURGERY. (E.) Bonchek, L. I. (NIH, Bethesda, Md.) and N. S. Braunwald. Ann. Surg. 165(3):420-424, 1967.

Experiences with the development and experimental application of a new tissue adhesive system consisting of gelatin-resorcinol-formaldehyde are reviewed. Advantages over the most widely used surgical adhesive, Eastman 910, include the ability to establish a rapid bond in the presence of moisture without the application of pressure, prolonged shelf life and high initial viscosity. The histotoxicity of the original adhesive system has been significantly reduced. Experimental evaluation of the adhesive for intestinal surgery was performed on 20 dogs. Transverse incisions in the distal ileum failed to heal in 7 of 8 control animals, but complete healing occurred in 10 of 12 animals in which the adhesive system was used to seal the incisions. Similar adhesive systems, in which glutaraldehyde or a glutaraldehyde-formaldehyde mixture was substituted for formaldehyde, also were evaluated. Both modified systems effectively controlled hemorrhage from the spleen in 12 dogs, but the glutaraldehyde-formaldehyde mixture seemed to maintain its bond strength in vivo more satisfactorily.

5846 A NEW NONOPERATIVE TECHNIC FOR THE
DIAGNOSIS OF PENETRATING INJURIES TO

THE ABDOMEN. (E.) Cornell, W. P. (926 E. McDowell Rd., Phoenix, Ariz.), P. A. Ebert, L. J. Greenfield and G. D. Zuidema. *J. Trauma* 7(2): 307-314, 1967.

Over a 2-yr.-period, penetrating abdominal wounds in 112 patients were evaluated by inj. sodium diatrizoate into the wound (60-80 ml) by way of a catheter in order to determine whether penetration of the peritoneum had occurred. Following inj. of contrast media abdominal roentgenograms were obtained in both recumbent and lateral positions. It is important to maintain high enough inj. pressure to permit the contrast media to follow the tract of injury. Of the 36 patients showing radiographic evidence of contrast media in the peritoneal cavity (6 with clinical signs of internal injury), all 36 showed peritoneal penetration at later surgery. None of the 20 patients (20 of 74 patients total) who originally showed no evidence of contrast media in the peritoneal cavity, demonstrated peritoneal penetration at subsequent surgery. Over a 16-mo.-period, none of the 54 patients from this same group demonstrated any clinical symptoms of intra-abdominal injury. Two of the 8 patients (including 1 repeat) with radiologically uninterpretable results showed no peritoneal penetration at laparotomy. No evidence of tissue necrosis or infection was associated with use of sodium diatrizoate which was quickly absorbed from the soft tissue. No prolonged pain or discomfit was experienced by patients in this series, although local and mild pain were noted during actual inj.

5847 RADIOGRAPHIC STUDIES OF THE GASTROINTESTINAL TRACT OF THE FETUS *IN UTERO*. (E.) Idriss, F. S. (Children's Mem. Hosp., Chicago, Ill.) and H. Nikaidoh. *J. Pediat. Surg.* 2(1):29-34, 1967.

Radiopaque material was instilled directly into the stomach by means of a silastic mesogastric tube following surgical exposure of the fetus in 50 pregnant dogs. Loss of amniotic fluid and disturbance of fetal-maternal relationships were minimized by employment of a latex well sutured to the wall of the uterus through which surgery was conducted. The well retained any amniotic fluid as well permitting studies to be carried out during early pregnancy. Roentgenograms were obtained at 15 and 45 min. after inj. of dye, hourly during the next day and daily until whelping occurred. Initial difficulties included difficulty in determining length of gestation in mongrel dogs, pulling out of the gastric tube, and the delicate condition of fetus at 3 wk. prior to whelping. Of the 22 successful gastrointestinal visualizations, there were 14 live births and 8 instances of *in utero* death, whereas there were 6 live births and 22 *in utero* deaths in the 28 cases of poor visualization. Filling of the small intestine was achieved in 30-60 min. while filling of the large intestine occurred in 3-4 hr. where the media stayed until birth. Fetal death and failure usually ensued when dye transit time was observed to be nil o too rapid.

5848 CINERADIOGRAPHIC EXAMINATION OF THE UPPER GASTROINTESTINAL TRACT IN OBSTRUCTIVE JAUNDICE. (E.) Adler, D. C. (201 Wilshire Blvd., Los Angeles, Calif.) and H. I. Meyers. *J.A.M.A.* 199(10):709-713, 1967.

Many clinicians consider the diagnostic accura of an upper gastrointestinal tract examination which is usually performed on patients with obstructive jaundice, to be quite low. A prospective study was undertaken to determine the diagnostic accuracy of the gastrointestina examination could be improved with the use of cineradiography; 61 patients thought to have obstructive jaundice were studied with the latter procedure. The diagnoses obtained were compared with pathological and clinical findin The diagnosis of periduodenal carcinoma was correctly made or excluded for 50 patients, giving an 82% accuracy level. These findings suggest that cineradiography provides a convenient method of complete recording of duoden changes that may be analyzed at length and in detail, and which can result in a higher degre of accuracy in the diagnosis of periduodenal carcinoma than is obtainable with conventional methods.

5849 SERUM AMYLASE AND LIPASE. NEWER PERSPECTIVES. (E.) Berk, J. E. (1721 Griffin Ave., Los Angeles, Calif.). *J.A.* 199(2):98-102, 1967.

A review is presented of recent advances in th methodology of serum amylase and serum lipase that enhance the clinical usefulness of these tests. A reliable micro-saccharogenic technic has been devised that allows measurement of amylase activity with small amounts of serum (as little as 0.01 ml). Amylase derived from the parotid gland can now be differentiated in serum from that originating in the pancreas; this suggests that other isoenzymes of amylase may soon be distinguished. Serum lipase can n be reliably assessed in small quantities of serum (0.05 mg) through the use of a newly-described micromethod. Abbreviations of the period of incubation required and improvements in technic now permit measurements of the activity of serum lipase to be made with greate sensitivity and rapidity.

32 PYURIA IN ACUTE INFANTILE DIARRHEA.

(E.) Gonzáles Alvarez, O. (San Juan
:y Hosp., Puerto Rico). Bol. Asoc. Med. P.
:o 58(11):533-538, 1966.

nples of urine from 385 patients with acute arrhea were studied; all were infants below 1 . of age and 71% were less than 4 mo. old. e incidence of pyuria was sharply reduced by llection of clean voided urine samples in astic bags, as compared with those routinely tained. Bacterial colony counts were performed on all of the clean voided samples (288) order to establish a correlation between such unts and the diagnosis of urinary tract fection; there was no satisfactory correlation d the data suggested a high degree of contamination by this method. Results indicate at by adequate cleansing the incidence of uria decreases, and they also corroborate the nding that below 1 yr. of age there is no sex fference in this finding. Use of neomycin did t influence the presence of pyuria, and there s no association between specific enteritis th Escherichia coli and an increased incidence urinary infection. Based on these findings, a udy has begun comparing clean voided samples urine with catheterized samples in order to rther investigate the most reliable method to recommended in establishing the diagnosis of inary tract infection in infants less than 1 . old suffering from acute diarrhea.

83 EXCRETION AND DETERMINATION OF THE PRESENCE OF POLYVINYLPYRROLIDONE IN
UDATIVE GASTROENTEROPATHIES. (EXPERIMENTAL
UDY). (It.) Lippi, U. (P. Cosma Civil Hosp.,
dua, Italy), E. Pulido and P. Trevisan.
oliclinico [Med.] 73(5):299-303, 1966.

10 male rabbits (1.5-2 kg) inj. i.v. with nonabeled polyvinylpyrrolidone (1 g/10 ml of aline), the excretion of the agent was studied nd its presence in the feces determined by ark-field illumination. In 5 rabbits (Group 1), nly the agent was admin. and animals were left ntact; in the other 5 (Group 2), animals were ubjected to digital compression of the proximal oops of the small intestine before the admin. f the agent. Animals of Group 1 showed no uminous bodies indicating the presence of polyinylpyrrolidone in either the intestinal wall r feces. On the other hand, the feces of nimals of Group 2 showed numerous luminous odies of polyvinylpyrrolidone. Microscopic tudies revealed damage to the intestinal wall ith both edema and hemorrhage of the subserous nd submucosal layers. Luminous bodies were lso observed in the interstitium between the lands, in the submucosal layer, in the intesinal lumen, and in the subserosal layer where lasma exudation was most apparent. Results onfirm the value of the Gordon test in xudative gastroenteropathies.

5884 THE SO-CALLED "PARACOLON" BACTERIA. A BACTERIOLOGIC AND CLINICAL REAPPRAISAL.

(E.) Fields, B. N. (U.S. Public
Health Serv., Atlanta, Ga.), M. M. Uwaydah,
L. J. Kunz and M. N. Swartz. Amer. J. Med.
42(1):89-106, 1967.

Evaluation of less well known Enterobacteriaceae including Serratia, Citrobacter, Providence, Hafnia, Edwardsiella and Arizona was completed with special emphasis on their clinical importance in bacteremia and infections of the urinary and respiratory tracts. These paracolon organisms represented 8% of all isolates of Enterobacteriaceae from blood and urine specimens and 23% of the sputum isolates. The number of patients with paracolons isolated from blood, urine and sputum specimens were, resp., 6, 43 and 22 patients for Serratia; 2, 74, and 55 patients for Citrobacter; 0, 35 and 2 patients for Providence. Hafnia strain was detected in urine (1) and sputum (2) specimens, while 3 patients with bacteremia attributable to Serratia were studied (primary site being the urinary tract in 2 patients and infected surgical wound in the third). Most of the isolates of Serratia, Citrobacter, Providence and Hafnia were etiologically significant in patients with urinary tract infections. Infections with the Providence strain showed a high incidence among young males. Most patients had a history of urologic procedure, asymptomatic pyuria, and prolonged antibiotic therapy. Underlying urologic disorders were especially predisposing to future infection in the Providence group. Paracolon isolation was frequently associated with chronic pulmonary disease (59 with pulmonary infection) with Citrobacter the only organism isolated at the onset of bronchopneumonia. Serratia and Citrobacter were associated with significant superinfection 30% and 9% of the time, resp. Negative correlation between existent pulmonary infection and paracolon isolation was observed in 22 patients studied. A case of significant superinfection in a 72-yr.-old woman caused by Serratia is described. Citrobacter strains were the most sensitive to antibiotic admin. (especially kanamycin and colistin). Bacteriology, clinical aspects, epidemiology, and antibiotic sensitivity is presented for Serratia, Providence, Citrobacter, Hafnia, Edwardsiella and Arizona strains.

5885 ISOLATION OF VIRAL DIARRHEA-MUCOSAL DISEASE COMPLEX VIRUS IN ITALY. A PRELIMINARY REPORT.

(E.) Castrucci, G. (U.
Perugia, Italy), V. Cilli and G. Gagliardi.
Boll. Ist. Sieroter. Milan. 45(11-12):533-538,
1966.

The isolation and identification of 2 strains of virus diarrhea virus (VDV), TVM1 and TVM2 from material collected in cattle affected by the virus diarrhea-mucosal disease complex (VD-MD) is reported. The virus was isolated in bovine embryo kidney cultures and its identity with the causative agent of the VD-MD complex was made on the basis of the following properties: 1) full sensitivity to pH 3, trypsin and chloroform; partial resistance to ether; and stability to 2'-(α-hydroxybenzyl)-benzimidazole; 2) neutralization by VDV C60F immune serum; 3) experimental pathogenicity for bovine and cross-immunity with VDV C60F; and 4) particle size of 57-58 mμ diameter and identity with the RNA virus group. According to serologic typing, performed with the 2 isolates plus some VDV strains from the United States (VDV C60F, VDV NADL, VDV 65/150), TVM1 and TVM2 were antigenically identical; 4 serotypes could be distinguished among the viruses tested.

5886 STUDIES ON DIARRHOEAL DISEASES IN SEVEN COUNTRIES BY THE WHO DIARRHOEAL DISEASES ADVISORY TEAM. (E.) Van Zijl, W. J. (World Health Organ., Geneva, Switzerland). Bull. WHO 35(2):249-261, 1966.

Incidence of diarrhea and isolation rates of Shigellae in children (data collected over a 1-mo. period in children 10 yr. of age) are reported from a series of separate studies over a 5-yr. period in Mauritius, Sudan, United Arab Republic (UAR), Ceylon, Iran, East Pakistan and Venezuela. The mo. rate of diarrhea, in areas having a water supply, was highest in Venezuela (39% with Iran second at 36%), whereas Iran showed a rate of 48.7% in areas deprived of water supply (43% for Venezuela). Sudan and UAR showed a high rate of diarrhea incidence and rate of enteropathogen detection similar to that of Iran. The low rates of diarrhea for both Ceylon and Mauritius, in view of local habits, were probably underestimations. A high diarrhea rate was observed in East Pakistan (20%), which also reported a high rate of protozoan and helminth isolation. Helminth and protozoan infestation was highest in Venezuela. Shigellae represented the largest group of enteropathogenic bacteria that was isolated in this study. Because of the generally high rates of helminth and protozoan infestation (especially in children who resided in high infestation zones), it is likely that the role of parasites in the incidence of diarrhea has heretofore not been fully appreciated in the countries evaluated. A combined statistical evaluation of all countries showed that the availability of water significantly reduced the incidence of diarrhea and detection rate of Shigellae, but not enough to solve the problem completely. The importance of water availability along with complete sanitation for reduction of diarrhea was emphasized. Other important factors observed in this study were the fly index and the mode of disposing of excreta. The dangers of improper sanitary method were emphasized. Helminth and protozoan infestation in preschool children was reported (Trichuris trichiura was the most common parasite isolated) according to organism type and age of the child. The limitations of antibiotic and s drug admin. and the proven benefits of breast-feeding (when compared to other foods) are reported.

5887 THE EFFECTS OF X RADIATION ON PERITONEAL HEALING: AN EXPERIMENTAL STUDY. (E.) Venables, C. (Westminster Hosp., London, S.W. 1), H. Ellis and J. E. Burns. Brit. J. Radiol. 40(472):275-279, 1967.

Adult white Wistar rats (18) were divided into groups of 3 each; each animal was laparotomize and a 1-cm^2 area of peritoneum was exposed; 5 groups were irradiated with doses from 250 r-5,000 r. Control rats received no irradiation. There was no apparent effect of irradiation, even at max. dosage, on the animal or healing a defect upon the opposite side. In a further group of 34 rats, peritoneum was exposed on bot sides, that on the right serving as the control A single dose of 1,500 r lasting 3.5 min. was admin. to the area of peritoneum on the left side. This dose of X-irradiation produced mark inhibition of local fibroblast proliferation in peritoneal wounds, but had no effect on the reconstitution of the serosal mesothelium. It is suggested, based upon this latter finding, that the newly-formed mesothelium is principall derived from free-floating cells in the peritoneal exudate.

5888 PREVENTION OF PERITONEAL ADHESIONS BY SILICONE SOLUTION. (E.) Aboulafia, and W. Z. Polishuk (Hadassah Med. Sch., Jerusalem, Israel). Arch. Surg. (Chicago) 94(3):384-387, 1967.

The ability of dimethylpolysiloxane fluid ('silicone') of a viscosity grade of 20 centistokes (1 centistoke is the viscosity of water) to prevent peritoneal adhesions after mechanical injury to the intestine was studied 50 rabbits. The standard injury used was an abrasion of the small intestinal serosal surfac over an area of 15-20 cm by 3-5 cm. Silicone i different amounts was then introduced into the peritoneal cavity, and results were assessed 10-21 days after the operation. All animals (1 in the control group developed Grade 4 adhesion In the group in which 50 ml silicone was used (14), no adhesions were found in 10 animals and very slight adhesions in 4. These results sugg that the mechanical separation of injured intestinal areas is an effective method of prevention of adhesions. Long-term toxicity studies must be done before silicone can be use as a mechanical barrier in human patients.

5889 PATHOGENESIS OF PERITONITIS. I. THE EFFECT OF Escherichia coli AND HEMOGLOBIN ON PERITONEAL ABSORPTION. (E.) Filler, R. M. (Walter Reed Army Inst. Res., Washington, D. C.) and H. K. Sleeman. Surgery 61(3):385-39 1967.

sorption of bacteria and colloidal protein
om the peritoneal cavity of white rats was
duced when lethal peritonitis was induced by
e addition of hemoglobin to an otherwise
nlethal *Escherichia coli* i.p. inoculation.
creased peritoneal absorption was shown by
termining, at selected times after infection,
absorption of dye-tagged protein from the
ritoneal cavity into the blood, and 2) the
mber of bacteria contained in the peritoneal
vity. Lethality of the *E. coli*-hemoglobin
oculum was attributed to the decreased
earance of bacteria from the peritoneal cavity,
ich allowed their continued growth and pro-
ction of soluble, absorbable toxins.

90 PATHOGENESIS OF PERITONITIS. II. THE EFFECT OF *Escherichia coli* AND
JUVANT SUBSTANCES ON PERITONEAL ABSORPTION.
.) Sleeman, H. K. (Walter Reed Army Inst.
s., Washington, D. C.), J. W. Diggs, W. S.
ndry and R. M. Filler. *Surgery* 61(3):393-398,
67.

he effects of *Escherichia coli* and adjuvant
ubstances on the peritoneal absorption of
vans blue dye-tagged protein were studied in
hite rats. Only those combinations of *E. coli*
nd adjuvant substances that resulted in plasma
ye conc. of 10 mg/liter or less were signifi-
antly lethal; this group included *E. coli* plus
emoglobin (lysed RBC or commercial), myoglobin
nd hog gastric mucin. Plasma dye conc. from
0-15 mg/liter were associated with morbidity in
he rats, but not with mortality. Included in
his group were *E. coli* plus phosphatidyl
thanolamine, sodium deoxycholate, gum traga-
anth, and mixtures of hemin and globin. *E. coli*
lus hemin, globin or polystyrene microspheres
ad much less adverse effect on peritoneal
bsorption and produced no deaths. Depression
f peritoneal absorption, as shown by plasma
onc. of dye, correlated well with lethality.

891 MEASUREMENT OF GASTROINTESTINAL PROTEIN LOSS USING CERULOPLASMIN LABELED
ITH ^{67}COPPER. (E.) Waldmann, T. A. (NCI,
ethesda, Md.), A. G. Morell, R. D. Wochner, W.
trober and I. Sternlieb. *J. Clin. Invest.*
6(1):10-20, 1967.

Ceruloplasmin labeled with ^{67}Cu and admin. i.v.
o dogs, control human subjects and patients
ith excessive gastrointestinal loss, fulfilled
he requirements for a label for quantification
of gastrointestinal protein loss. The radio-
copper moiety was poorly absorbed from the
gastrointestinal tract, not actively secreted
into the intestinal tract and did not alter
significantly the metabolism of ceruloplasmin.
Approx. 70% of the body pool of ceruloplasmin in
both man and dog was within the intravascular
space. The mean ceruloplasmin conc. in control
human subjects was 30 mg/100 ml, with the total
circulating and total body ceruloplasmin pools being 15.5 and 22 mg/kg, resp. In patients with excessive gastrointestinal protein loss secondary to intestinal lymphangiectasia, the serum ceruloplasmin conc. was reduced to 16 mg/100 ml with a comparable reduction in the total circulating and total body ceruloplasmin pools to 8.8 and 12 mg/kg, resp. The survival half-time of ceruloplasmin was 6.1 days in normal human subjects; it was 4.5 days in normal dogs. From 1.0-1.9% of the intravascular pool of ceruloplasmin was lost into the gastrointestinal tract of the dog per day; this represented less than 11% of the overall metabolism of this protein. In control human subjects, from 1.9-3.9% of the intravascular pool was lost into the gastrointestinal tract each day; this represented a max. of from 11-22% of the overall metabolism of this molecule. Patients with intestinal lymphangiectasia, in contrast, had a markedly shortened ceruloplasmin survival of 3.1 days, with from 15-40% of the intravascular pool of ceruloplasmin cleared into the gastrointestinal tract daily; this represented 76% of the overall metabolism of this protein. It is concluded that although bulk loss of serum proteins into the gastrointestinal tract does not normally appear to be a significant factor in protein metabolism in normal man and dogs, such a loss is a major factor in the pathogenesis of the hypoceruloplasminemia noted in patients with intestinal lymphangiectasia.

5892 GASTROINTESTINAL OBSERVATIONS IN ROSACEA. (E.) Marks, R. (St. George's Hosp., London), R. J. Beard, M. L. Clark, M. Kwok and W. B. Robertson. *Lancet* 1(7493): 739-743, 1967.

Study of 62 patients with rosacea and 62 control patients with other skin disorders showed no difference in the prevalence of gastrointestinal disease or symptoms in the 2 groups. Rosacea patients were significantly heavier than controls. The diet in 33 rosacea patients and 33 control patients did not differ significantly. Gastric biopsies in 18 rosacea patients and 16 control skin patients showed no demonstrable differences, and jejunal biopsies from 34 rosacea patients and 34 patients with other skin diseases revealed no demonstrable abnormality. One reason for the belief that pathogenesis of rosacea is linked with gastrointestinal disorders may be that patients with rosacea flush more frequently and more easily when eating or drinking than do controls.

5893 VIRAL AGENTS IN GASTROINTESTINAL DISEASE. (E.)(Rev.) Cheever, F. S. (U. Pittsburgh, Pa.). *Med. Clin. N. Amer.* 51(3): 637-641, 1967.

7 ACHALASIA OF THE ESOPHAGUS: A STUDY OF ESOPHAGEAL MOTILITY IN ACHALASIA NORMAL INDIVIDUALS AND A FOLLOW-UP STUDY ON NTY-FIVE PATIENTS WITH ACHALASIA TREATED BY PHAGOMYOTOMY. (Jap.) Imai, Y. (Keio U. Sch. ., Japan). *Nippon Kyobugeka Gakkai Zasshi* *Jap. Ass. Thorac. Surg.*) 15(1):1-13, 1967.

ements of the esophagus were examined by ns of the cinefluorography and manometric hod in 30 normal subjects and 32 patients h achalasia of the esophagus; of the latter, were operated upon and the movements were pared before and after the operation. The ration was usually (in 25 cases) performed ording to the modified Petrovsky's diaphragmo- sty technic, and satisfactory results were ained in all but 1 case. A correlation was nd between the degree of esophageal dilatation duration of the symptoms, as expressed in following equation: Dilatation index = 3.1 (years of duration) x 54 (V = 0.78). Resting ssures in the thoracic esophagus in the ients with achalasia were higher than those the controls, the preoperative mean value ng +4.7 ± 1.7 mm Hg, while control value was .7 ± 0.6 mm Hg, both as compared with the aryngeal pressure of each group. After the eration, the resting pressure decreased idly to reach -0.6 ± 0.7 mm Hg, as compared th the pharyngeal pressure. A reverse rrelation was found between the max. plitude of non-peristaltic contraction and age the patients, but no significant correlation s found between contraction and dilatation. ter the operation, the size of the esophagus parently decreased. The dilatation index 1 . after the operation was closely correlated the preoperative index (V = 0.95), as ex- essed as postoperative index = 1.2 x (pre- erative index) - 42.

88 ANATOMIC LOCATION OF THE LOWER ESOPHAGEAL RING. (E.) Johnston, H., Jr. (U. Mississippi Sch. Med., Jackson) d J. C. Griffin, Jr. *Surgery* 61(4):528-534, 67.

etrograde esophagoscopy at the time of surgery 11 cases (5 women, 6 men; 40-62 yr. old) of e lower esophageal ring (10 of which were ssociated with hiatal hernia) showed that in 4 e ring was located at the true cardia or sophagogastric junction; in 2 it was found 2 above, and in 3, 3 cm above; in the remaining , it was located 5 cm above the anatomical sophagogastric junction. These results are at ariance with the commonly accepted view that uch rings uniformly occur at the gastric cardia d are valuable radiologic landmarks. In all cases, the rings occurred at the junction of quamous and glandular epithelium; thus, in 7 he distal esophagus was lined with gastric pithelium (gastroesophagus). Four of 10 had an associated duodenal ulcer, past or present; the remaining patient had an intractable postbulbar duodenal ulcer with a lower esophageal ring 4 cm within the esophagus and no hiatal hernia. Esophagitis, past or present, was recorded in 7 of 11; this is contrary to the accepted view that rings are unassociated with clinical or radiological evidence of esophagitis. All had a history of dysphagia, and in 3 it was marked. All were operated on by the transabdominal approach. In 9 patients the ring was digitally dilated through a small gastrostomy opening, one other underwent pneumatic dilatation and another retrograde dilatation with bougies. In 9 of the 11, truncal vagotomy and Heinicke-Mikulicz pyloroplasty were done; vagotomy and hemigastrectomy were performed in the remaining 2 because of severe duodenal ulcerative disease. The incidence, clinical picture (illustrated with 1 case report) and pathology of lower esophageal ring are also discussed.

5989 OPENING OF THE CARDIA AND HIATUS HERNIA. (E.) Johnson, H. D. (Roy. Postgrad. Med. Sch., London). *Surgery* 61(2): 177-182, 1967.

The physiology and mechanism of opening of the cardia and hiatus hernia was studied in experiments on 5 dogs and during 193 operations for hiatus hernia. Of the latter, only patients with paraesophageal hernias all had conspicuously large hiatuses; in most of those with sliding hernias with the cardia at the apex, the hiatus was within normal limits. Of 161 hernia patients operated on abdominally, 20 (12%) had gallstones. Duodenal ulcers alone were found together with hiatus hernias 24 times (14 in patients operated on primarily for the ulcers). Seven patients had gastric ulcers, but 5 of these also had either duodenal ulcers or their scars; 1 had adult pyloric hypertrophy. The formula PI-PE = T/R (where PI and PE are pressures inside and outside of a nonrigid tube, T is the tension in its wall and R is its radius) is useful in understanding opening of the cardia. The abdominal esophagus closes and resists reflux if the total compression of its lumen (PI) exceeds intragastric pressure; PE is the same for both organs. Therefore, for PI in the esophagus to exceed PI in the stomach, TE must exceed TS x DE/DS (where TE and TS are tensions in the walls of esophagus and stomach, resp., and DE/DS is the ratio of the effective diameter of the esophagus to stomach). However, when the terminal esophagus is wholly intrathoracic, it is subjected to lower external pressure than the stomach. In order to close, the sphincter must now exert, in addition, sufficient compression to overcome the difference between intra-abdominal and intrathoracic pressure. When this is high, as in recumbancy, the sphincter may give way. Opening of the cardia is an active process and involves elevation; this tents and parts the mucosal folds, and also eliminates the abdominal esophagus. It caused substantial hiatal herniation in dogs. Pathological reflux occurs as soon as the abdominal esophagus is extruded into the chest. Secondary esophageal spasm is then held to encourage further elevation of the cardia; such elevation also accompanies biliary stimulation. It is suggested that this represents vigorous opening of the cardia as part of the vomiting reflex; this is considered an additional factor in the pathogenesis of hiatus hernia complicating gallstones, peptic ulcer or pregnancy.

5990 LATE RECOGNITION AND TREATMENT OF TRAUMATIC DIAPHRAGMATIC HERNIAS.

(E.) Schwindt, W. D. (U. Wisconsin Med. Ctr., Madison) and J. W. Gale. Arch. Surg. (Chicago) 94(3):330-334, 1967.

Twelve patients (22-63 yr. of age) with ruptured diaphragms (all but hernia were in left thorax) resulting from trauma were examined between 1 mo.-10 yr. after injury. Five patients with asymptomatic pictures had abnormal thoracic roentgenograms, while thoracopulmonary symptoms (shortness of breath, exertional dyspnea and chest pains) and gastrointestinal symptoms (nausea, mild vomiting, wt. loss and infrequent constipation) were present in the other 3 and 2 patients, resp. Of the 7 patients with fractures (4 with pelvic and 6 with costal fractures), 5 had sustained automobile injuries. One patient had persistent pneumothorax. Routine thoracic films were confirmatory in 7 patients, while employment of upper gastrointestinal X-ray, Ba enema and diagnostic pneumoperitoneum were necessary for positive diagnosis in the other 7. The colon, either with omentum or spleen (or both), was the most common abdominal organ found within the thorax, while the stomach was second in frequency. In 2 patients, the stomach, colon, omentum, spleen and a large portion of the small intestine were seen in the thorax. Eleven patients underwent a successful thoracotomy for reduction and repair of the hernia. Two patients from this group had abdominal procedures which proved unsuccessful due to massive adhesion formation. The twelfth patient (10 yr. after injury) refused surgery despite the presence of his liver in the right thorax. There were no operative complications or deaths in this series.

5991 THE ANATOMICAL BASIS FOR THE RADIOLOGICAL DIAGNOSIS OF MINIMAL HIATAL HERNIATION.

(E.) Berridge, F. R. (Addenbrooke's Hosp., Cambridge, England) and G. W. Friedland. Irish J. Med. Sci. 6(494):51-62, 1967.

The gastro-esophageal junction was examined in 132 cadavers and 7 instances of hiatus hernia were found which did not compare favorably with corresponding radiological findings. The primary importance of the phreno-esophageal membrane in anchoring the stomach in the abdomen is stressed. When this membrane is intact (though elastic) it is impossible to pul the gastro-esophageal junction above the hiatus at autopsy. In many normal persons, the mucosa junction does pass above the hiatus (usually during deep inspiration or when the stomach is pushed up). The position of the lower esophagu and hiatus as well as the function of the vestibule, especially during different phases of breathing, were studied by means of radio-opaque markers. The function of the vestibule seems to be the formation of an intermediate chamber between the stomach and the esophagus which permits the passage of food into the stomach when the intragastric pressure greatly exceeds that of the intrathoracic pressure. Failure to realize the existence of the 3 different vestibular states (relaxed, contracte and closed) has resulted in the problem of whether there is an anatomical sphincter at the lower esophagus. In determining a minimal hiatal herniation one must find the mucosal fol at the gastroesophageal junction above the hiatus and distinguish it then from the inferior esophageal sphincter which normally lies above the diaphragmatic hiatus.

5992 ACID SECRETION IN SYMPTOMATIC SLIDING HIATUS HERNIA.

(E.) Williams, C. B. J. H. Lawrie and A. P. M. Forrest (Roy. Infirm. Cardiff, Wales). Lancet 1(7483):184-185, 1967.

Max. outputs of acid were estimated by the histamine infusion test in 37 unselected patients with sliding hiatus hernia and in 30 patients without dyspeptic disorders. Seven of the hiatus hernia patients also had duodenal ulceration. The av. basal output of hiatus hernia patients without duodenal ulcer was 1.47 mEq/hr. compared to controls of 1.26 mEq/hr. Following histamine the values were 19.9 mEq/hr compared to control levels of 19.9 mEq/hr. Hernia patients with ulcer had av. basal value of 3.07 mEq/hr. and 37.1 mEq/hr. following histamine. The acid outputs of the hiatal hernia patients with duodenal ulcer fell in the range of patients with only ulcer. When the patients were subdivided according to the number of their symptoms, no relation was found between the number of symptoms and the max. output of acid, nor was the severity of the symptoms related to acid output. In 10 patient in whom operation was necessary the max. output was 22.8 mEq/hr. as against 23.2 mEq/hr. in 27 patients in whom operation was not considere necessary. It is concluded that if vagotomy is of benefit to hiatal hernia patients, it is beneficial by reducing the secretion of acid from a level which is within the normal range.

5993 A NEW DOUBLE-CONTRAST METHOD IN ESOPHAGEAL ROENTGENOLOGY.

(E.) Wiljasalo, M. (Univ. Cent. Hosp., Helsinki,

and) and P. Rissanen. Ann. Med. Intern.
. 55(3):77-80, 1966.

ng 2.5% Na methylcellulose with some sorbitol
ed as a roentgen-negative material and micro-
st as the roentgen-positive contrast, a new
ble-contrast method in esophageal radiology
developed. While standing, the patient
st must swallow a spoonful of microtrast and
n a spoonful or two of Na methylcellulose.
pictures in the anteroposterior as well as
the oblique direction are taken in rapid
cession. Using this method 10 normal sub-
ts, 32 nonradiated cases of esophageal
cinoma, 50 radiated esophageal carcinomas, 10
ices of the esophagus, and 5 cases of hiatus
nia were examined. Upon analysis, the normal
phagus appears more dilated in the erect
ition than when examined by the usual methods.
relief of the mucous membrane is clearly
ible and the diverticula are well dilated.
the examination of incipient carcinomas, the
ble-contrast method is of particular impor-
ce since a depression in the wall is often
ceptible only in one projection. This
roach was especially valuable in the detection
localization of the carcinoma (being helpful
diagnosis in approx. 75% of 127 patients
mined). Improved information concerning
tus hernia was not obtained using this
hod.

94 THE INK-WELL ANASTOMOSIS IN OESOPHAGEAL
RECONSTRUCTION. (E.) Procter, D. S. C.
ivingstone Hosp., Port Elizabeth, South
ica). S. Afr. Med. J. 41(8):187-191, 1967.

30 patients subjected to "ink-well" anastomosis
r treatment of advanced carcinoma of the
ophagus, none died as the result of anastomotic
akage. Elimination of such leaks depended for
e most part on a considerable emphasis of the
gmental blood supply to the esophagus during
rgery. Avoidance of unnecessary mobilization
ring surgery, complete absence of any stress
ong the suture line and the presence of a
condary barrier to leakage in the form of a
ritoneal seal are other primary considerations.
e anastomosis consisting of 2 posterior and 2
terior rows of sutures are sufficient with the
ture line including all coats of both struc-
res, especially the mucosa. Tendency for
gurgitation may be diminished by employing
ch an "ink-well" configuration. All 6 opera-
ve deaths resulted from postoperative acidosis
), pulmonary collapse (2), cerebrovascular
cident (1), massive aortic hemorrhage (1) and
erative shock (1). There was 1 instance of
oughing of colon (bypass procedure) after
ich the patient remained healthy for 5 mo.,
fore succumbing to pulmonary tuberculosis.
akage in the neck occurred on the ninth
stoperative day in 1 patient in whom bruising
f the colon had occurred during surgery, and
this leak closed spontaneously after 2 weeks, without stricture formation. Four patients died during follow-up after periods of 10 wk., 5 mo., 9 mo., and 14 mo., resp., with normal swallowing and full diet being characteristic of the last two and all 20 remaining patients. At autopsy no esophagitis or stenosis of the esophagus was observed in the one surviving 14 mo.

5995 THE "CAPTIVE BOLUS" TEST AND THE PINCHCOCK AT THE DIAPHRAGM. AN ESOPHAGEAL PUMP AND SOME NON-DISEASES OF THE ESOPHAGUS. (E.) Stiennon, O. A. (St. Mary's Hosp., Madison, Wisc.). Amer. J. Roentgen. 99(1):223-232, 1967.

A new and simple procedure, the "captive bolus" test, is described; it gives a measure of the phrenoesophageal ligament and helps to explain the "wing" and "Saturn ring" signs. The latter is due to a pinching off of the circumference of the gastric tube as it begins to reduce; the former sign is due to an aperistaltic segment which is flattened between the lower esophageal ring and sphincter by the pinchcock pump. This test also indicates that most, if not all, reported cases of "orthograde prolapse of the esophageal mucosa" and "retrograde prolapse of the gastric mucosa" are false. The cause of the pinchcock at the diaphragm is explored and the existence of a hitherto undescribed, hydraulically actuated, retrograde pump at the cardia is described and analyzed. This pump may be significant in accounting for pyrosis in certain cases of hiatus hernia.

5996 INSTRUMENTAL RADIOLOGICAL DIAGNOSIS IN THE CORRELATION OF PORTAL HYPERTENSION WITH VICARIOUS GASTROESOPHAGEAL CIRCULATION. (It.) Porta, E. (U. Naples, Italy), E. Verrengia, P. Cappabianca and M. Crocco Egineta. Ann. Radiol. Diagn. (Bologna) 39(2):93-166, 1966.

In an effort to correlate the relationship existing between portal hypertension and vicarious gastroesophageal circulation, results of various methods of radiological examination are reported in 166 patients with esophageal varices. Conventional esophagography revealed a picture ranging from slight irregularities of the esophageal margin to a completely irregular structure of the mucosa, which appeared lacunar or polypous. Esophagography combined with roentgencinematography revealed important data regarding esophageal tonus and peristalsis as well as Ba transit. Both intra- and extrahepatic alterations were studied by means of splenoportography with splenomanometric control. Important portal pressure changes were observed by catheterization of the suprahepatic veins. Data on intrahepatic blood vessel alterations were obtained by retrograde venous hepatography, or epihepatography. Selective celiacography proved valuable in obtaining data on the behavior of the hepatic and splenic arterial blood supply in patients with hepatic cirrhosis. It is concluded that the development of esophageal varices depends not only on the degree of portal hypertension but on other factors (portal blood vessel morphology, resistance of blood vessel walls) as well. The technic of each method is described and illustrative X-rays are presented.

5997 THE CRURAL BRANCHES OF THE PHRENIC NERVES. THEIR SURGICAL SIGNIFICANCE. (E.) Wynyard, M. and H. D. Kletschka. Minnesota Med. 49(12):1821-1824, 1966.

The terminations of the crural branches of the phrenic nerve are illustrated and described. Based upon the pattern of innervation, it is proposed that crural musculature to the left of the esophagus be referred to and considered as the left crus; and similarly, the crural musculature to the right of the esophagus be identified as the right crus. Terminal branches of the crural nerves are distributed mainly to that portion of each crus situated caudad to the midlevel of the esophageal hiatus and are closely associated with the margin of that hiatus. In dealing surgically with the esophageal hiatus, injury to the crural nerve terminal branches will most likely occur in those cases in which the hiatus is closed posteriorly to the esophagus. Due to the superficial course which the nerves take on the abdominal aspect of the crura, an abdominal approach increases the hazard in such repairs. These postulates are of special importance in hiatal hernia and reflux esophagitis (when it should be determined whether previous injury to the phrenic nerve has occurred).

6030 MITOTIC ACTIVITY AND RENEWAL RATE OF EPITHELIAL CELLS OF DIGESTIVE TRACT IN CANCER PATIENTS. I. OBSERVATION ON THE STOMACH AND DUODENUM IN THE PATIENTS WITH GASTRIC CANCER OR PEPTIC ULCER. (E.) Suzuki, K. (Yamaguchi U. Sch. Med., Japan). Gann 57(5):453-466, 1966.

To ascertain mitotic activity, at least 2000 cells were counted in each of the gastroduodenal tissues removed by surgery from 50 patients with various diseases. The mitotic activity of gastroduodenal epithelium of gastric cancer patients was lower than that of noncancer patients. To obtain high mitotic values and turnover time of human gastroduodenal epithelium, the Colcemid (demecolcine) technic was used after preliminary studies with rats. Patients (72) with various gastrointestinal lesions were inj. with 0.15 mg/kg of Colcemid i.v. 3-7 hr. before gastrectomy. The difference in mitotic values between gastric cancer and noncancer groups was highly significant. On the basis of the mitotic values obtained by the Colcemid technic, the turnover rates were calculated. In gastric cancer patients turnover time was 7 days in the body mucosa, 4.7 days in the pyloric mucosa, and 4.5 days in the duodenal mucosa. In the noncancer patients the renewal times of pyloric and duodenal mucosa were about 2.4 and 2 days, resp.

6031 MITOTIC ACTIVITY AND RENEWAL RATE OF THE EPITHELIAL CELLS OF DIGESTIVE TRACT IN CANCER PATIENTS. II. MITOTIC RATE OF THE EPITHELIAL CELLS OF BUCCAL MUCOSA IN THE PATIENTS WITH CANCER OF VARIOUS ORGANS. (E.) Suzuki, K. (Yamaguchi U. Sch. Med., Japan). Gann 57(5): 467-475, 1966.

Low mitotic activity of gastric and duodenal mucosa in the cancerous stomach compared to normal was reported in the preceding paper. In the present study specimens of buccal mucosa were taken in connection with operation on various organs in 98 patients, 6-7 hr. after the admin. of Colcemid. Approx. half the patients suffered from cancer. Mitotic counts were made in the mitotic area of the mucosa after appropriate preparation and sectioning. Almost all the specimens in the cancer group showed less mitotic counts than the noncancer specimens. The mitotic rate of the buccal mucosa was not influenced by age or sex in the cancer group, as was observed in the gastric and duodenal mucosa in the earlier study. Regression with age did occur in the noncancer group. Only 6 patients of the noncancer group showed a mitotic rate less than 2%. It is suggested that the mitotic activity of tissues may be suppressed in the cancer-bearing individuals by an unknown factor. Two cases were reported which showed low mitotic rates of buccal mucosa but were not found to have cancer; later both were found to have cancer.

6032 GASTROSTOMY IN POSTOPERATIVE DECOMPRESSION. INDICATIONS AND METHODS. (E.) Cox, W. D. (VA Hosp., Chicago, Ill.) and W. J. Gillesby. Amer. J. Surg. 113(2):298-302, 1967.

A technic for tube gastrostomy was developed and used in 305 patients. The muscle fibers of the anterior wall of the stomach are separated by blunt dissection allowing the mucosa to bulge in the opening. The mucosa is incised and the muco edges elevated, a Foley catheter passed into the stomach and a chromic catgut ligature tied aroun the mucosa and tube. Purse-string sutures are placed and the gastrostomy opening inverted. In some cases a radial purse string suture is used. The tube is passed to the exterior via a stab wound and the stomach wall sutured to the peritoneum. A double-lumen tube can be similarl placed with the smaller lumen placed into the duodenum for simultaneous drainage of both stoma and duodenum. A 40-inch Foley catheter can be propelled through the distended intestine with low suction applied as an aid in decompression. In recurrent mechanical obstruction the tube can be left in place preventing acute angulation of the intestine until the return of peristalsis. By connection of the gastrostomy tube with a biliary T-tube, bile is returned to the stomach and duodenum without unpleasantness for the patient, and anorexia, weakness and failure to gain wt. is prevented.

6033 STUDIES OF NUTRITIONAL INSUFFICIENCY IN GASTROSTOMIZED CHILDREN. (Fr.) Savic, D. (U. Belgrade, Yugoslavia), B. Mihaljev and E. Stojimirovic. Acta Otorhinolaryng. Belg. 21(1):76-82, 1967.

Metabolic studies were performed on 20 children with lye-induced esophageal scarring, who had undergone gastrostomy 2-6 mo. later after dilata tion failed (age 1-4 yr.) and had been hospitali 2-6 times thereafter for 6 mo.-2 yr. All childr were on adequate diets, but all were below av. i height and wt. Osteoporosis and retarded bone growth were noted in 11 patients (in 3 of these, bone growth was retarded 2-4 yr.); none showed "hunger edema." Serum proteins were normal (no hypoalbuminemia was present), but hemoglobin levels were decreased in 11 patients and serum iron in 12 (about 30 μg% in 3 cases). Infectiou diseases were frequent; most of the children wer inactive and spent the day in bed. Gastric secr tion was normal in only 5 patients; hypochlorhydria was present in 5 and achlorhydria in 8 (histamine-resistant in 2). Marked depression o protein metabolism because of deficient gastric (and perhaps also pancreatic) secretion was evident.

6034 FACTORS INFLUENCING THE PSYCHIC DEVELO MENT OF GASTROSTOMIZED CHILDREN. (Fr.

vic, D. (U. Belgrade, Yugoslavia), H. Rot,
. Mihaljevic and E. Stojimirovic. Acta
torhinolaryng. Belg. 21(1):83-90, 1967.

sychological studies were performed in 29 children
age 9 mo.-9 yr.) who had undergone gastrostomy
t age 5 mo.-6 yr. (usually age 1-4 yr.) following
orrosive injury to the esophagus; the av. dura-
ion of the condition was 3 yr. and the children
ad been hospitalized on 2-5 occasions (av. 3)
or an av. of over 8 mo. All children were from
rural district or small towns and their families
ere of about the same socio-economic status.
sychomotor development was significantly retarded;
he I.Q. was 76 in 3% of the group, 84-87 in 25%,
0 in 20% and 90-100 in 48%. The children were
asily approached by strangers, highly suggestible,
pathetic and passive (even when about to undergo
ilatation); speech was poor, vocabularies were
mall, and behavior was stereotyped. Figure-
rawing tests in the older children indicated
hat this retardation resulted not only from the
ccasional symptoms noted (e.g., pain) and from
rolonged separation from the family, but also
rom the gastrostomy itself and the periodic
ilatations required, which apparently produced
chronic emotional stress that retarded intellec-
ual and psychic development. These findings
ere in significant contrast to those obtained in
comparable group of children hospitalized for
uberculosis.

6035 FATE OF AUTOTRANSPLANTED STOMACH MUCOSA FOLLOWING TOTAL GASTRECTOMY IN DOGS. (E.) Payan, H. M. (VA Hosp., Clarksburg, W. Va.), W. H. Gerwig, Jr., C. Mendoza, Jr., B. Zimmermann and W. S. Albrink. Arch. Path. (Chicago) 83(3):298-306, 1967.

Mongrel dogs were subjected to total gastrectomy. Under sterile conditions, the mucosa was stripped from the proximal and middle thirds of the stomach; the fundic third was transplanted in the right axilla and the middle third of the stomach in the left axilla. Serial biopsies were taken from the transplanted gastric mucosa at intervals of days, wk. and mo., and were studied morphologically and histochemically. Earlier biopsies revealed degeneration of the epithelial elements of the mucosa with inflammation and granulation tissue of the submucosa and muscularis mucosa. Cuboidal epithelial cells were observed after a wk., with gradual change into tall columnar cells; these cells showed a marked morphologic and histochemical resemblance to the normal mucus cells of the stomach. Preservation of the mucosal and submucosal connective tissue appeared to be an important element in regeneration of the epithelial cells. The physiologic activities of the grafts were attributed to the mucus cells of the stomach.

6036 ROLE OF 5-HYDROXYTRYPTAMINE IN THE DUMPING SYNDROME AFTER GASTRECTOMY: HISTOCHEMICAL STUDY. (E.) Tobe, T. (Japan Baptist Hosp., Kyoto), C. Kimura and M. Fujiwara. Ann. Surg. 165(3):382-387, 1967.

The cytological localization of serotonin and catecholamines in the human gastrointestinal tract was demonstrated,,using a specific fluorescence technic for demonstrating biogenic monoamines. Many serotonin-containing cells were found in Lieberkühn's crypts in the duodenum and jejunum. Intrajejunally admin. hypertonic glucose soln. induced a complete to near-complete release of serotonin in all cases. In accord with the release of serotonin many gastrectomized patients to whom hypertonic glucose was given during a glucose tolerance test complained of nausea or abdominal pain with palpitation. In severe cases, signs and symptoms resembled the dumping syndrome. It is suggested that, after gastrectomy, a liquid diet can flow very promptly from the stomach without a pyloric ring into the duodenum or jejunum and then induce considerable release of serotonin which results in the dumping syndrome in serotonin-sensitive patients.

6037 THE ROLE OF BRADYKININ IN VASOMOTOR ASPECTS OF THE CARCINOID AND DUMPING SYNDROMES. (E.) Smith, A. N. (U. Edinburgh, Scotland) and I. J. Zeitlin. Brit. J. Surg. 53(10):867-869, 1966.

Bradykinin and its precursor extracted from blood samples drawn from various patients were assayed using the estrous rat uterus. All assays were performed against a pure standard. In 4 carcinoid cases kinin was found to increase in blood drawn during flushing; there were no rise in kinin level without vasomotor symptoms. Dumping attacks were provoked by glucose in 4 fasting gastrectomy patients. All 4 complained of postprandial malaise, flushing, sweating, headache and abdominal discomfort. Attacks of dumping occurred 10-15 min. following glucose. The kinin level increased at the height of an attack (controls of approx. 0-2 ng/ml to approx. 60-108 ng/ml) but fell rapidly returning to normal levels at the completion of an attack. Patients given a large volume (250 ml) of saccharin-sweetened soln. showed neither symptoms nor increased kinin levels. Normal subjects on whom no gastric surgery had ever been performed did not release kinin when given dumping provocation with glucose soln. The degree of the clinical effects seen was correlated with the amount of kinin released. The site of the release of kinin has not been established; it was pointed out that its formation may be activated in the circulation or in other tissues anywhere in the body.

6038 A PHYSIOLOGICAL APPROACH TO THE SURGICAL TREATMENT OF THE DUMPING SYNDROME. (E.) Stemmer, E. A. (5901 E. 7th St., Long Beach, Calif.), J. M. Guernsey, R. E. Heber and J. E. Connolly. J.A.M.A. 199(12):909-913, 1967.

An intractable form of the dumping syndrome developed in 2 patients after vagotomy and pyloroplasty, and they were successfully treated by the interposition of an antiperistaltic segment of jejunum between the stomach and duodenum. Gastrointestinal motility studies were performed before and after the surgical procedures in 1 patient. The effectiveness of the interposition operation in preventing the gastrointestinal and vasomotor reactions to the experimentally provoked dumping syndrome was studied in a group of dogs in which jejunal reversal had been performed distal to a Mann-Bollman fistula of the duodenum. Jejunal interposition lessened or abolished both the subjective and objective responses in the patients and in the experimental animals.

6039 SEROTONIN AND THE DUMPING SYNDROME.

(E.) Reichie, F. A. (3401 N. Broad St., Philadelphia, Pa.), P. Brigham and G. P. Rosemond. J.A.M.A. 199(12):914-916, 1967.

Consistent increases in peripheral serotonin levels in platelet-rich plasma were seen in 14 patients with the dumping syndrome who were given hyperosmotic glucose p.o. Similar changes in peripheral serotonin levels occurred in 6 patients with normal gastrointestinal tracts after the intraduodenal instillation of hyperosmotic glucose. Almost no change was seen in control patients after p.o. admin. of the same test meal. Hematocrit changes occurred consistently in the test group, but these were smaller than the increases in serotonin; this indicated that the serotonin changes were not merely reflections of hemoconc. Assays of serotonin done on platelet-rich plasma, which is thought to provide max. sensitivity and reliability, together with the admin. of a large dose of hyperosmotic stimulus, enabled the detection of an index in peripheral venous blood of serotonin release into the circulatory system from the gastrointestinal tract. Therefore the release of serotonin into the circulatory system does accompany the dumping syndrome; however, it remains to be determined whether the increases are sufficient to account for all of the symptoms.

6040 GASTROSTOMY WITH A PROSTHESIS. (E.)

Redo, S. F. (New York Hosp.-Cornell Med. Ctr., N. Y.) and W. A. Barnes. Surgery 61(2):320-324, 1967.

A description is presented of a refined technic of creating a permanent gastrostomy by means of a prosthesis previously described; in addition, the results of 51 gastrostomies using this prosthesis done at the New York Hospital and an additional 30 done at other institutions throughout the United States are described. Of 51 gastrostomies done at the New York Hospital, patients included 33 men and 18 women (25-86 yr. old, with an av. age of 63 yr.; 41 were 50-80 yr. old). Follow-up ranged from less than 1 wk. to 6 yr. postoperatively. The fatal complication rate was 1 of 51 (2%); this was due to operative procedure and not to the prosthesis *per se*. The nonfatal complication rate was 4 of 51 (7.8%), and included slight wound infection in 1, minimal leakage about the prosthesis in 1, mild skin excoriation about the prosthesis in 1 and extensive infectio and leakage in 1, that was controlled and cured by meticulous local care. A review of 54 gastrostomies done by other methods at New York Hospital before 1956 revealed a nonfatal complication rate of 37%. In 3 instances, the gastrostomy was no longer required and the prosthes was removed without incident 3-18 mo. after insertion; this followed X-ray treatment in the first patient, retrograde bouginage in the secon and resumption of the ability to swallow in the third. The results of use of the prosthesis in the additional 30 patients were similar; none of the gastrostomies was accompanied by infection o leakage, and all functioned well during the follow-up periods of from 1-19 mo. It is conclu that gastrostomy using this plastic prosthesis is a simple, safe and satisfactory method of fee ing, usually unaccompanied by leakage, discomfor infection or skin irritation.

6041 BLIND POUCH SYNDROME. A COMPLICATION OF SIDE TO SIDE INTESTINAL ANASTOMOSIS

(E.) Botsford, T. W. (Peter Bent Brigham Hosp., Boston, Mass.) and A. B. Gazzaniga. Amer. J. Surg. 113(4):486-490, 1967.

Three cases of the "blind pouch" syndrome with severe anemia due to intestinal bleeding are described. The "blind pouch" syndrome may be defined as a series of symptoms associated with formation of a blind pouch secondary to side-to-side intestinal anastomosis; it should be distinguished from the "blind loop" syndrome. Symptoms associated with the formation of the blind pouch include anemia, diarrhea, failure to gain wt. and intermittent abdominal pain. Treatment of this complication is excision of the lateral anastomosis followed by end-to-end anastomosis of the normal intestine.

6042 DISTURBED GLUCOSE TOLERANCE IN SUBTOTAL GASTRECTOMY.

(E.) Alpert, S. (VA Reg. Office, New York City), F. Kerrigon and R. Berke. Amer. J. Gastroent. 47(3):215-220, 1967.

Glucose tolerance tests were performed p.o. on 34 gastrectomized subjects and 31 patients with chronic duodenal ulcer without gastric resection. An i.v. glucose tolerance test was given to 6 gastrectomized patients. The characteristic pattern of initial hyperglycemia followed by a sharp descent to hypoglycemic levels was observed in 21 cases of gastrectomized patients. Similar changes, to a lesser degree, were noted in the medically-treated cases of duodenal ulcer. Such changes were not seen with the i.v. admin. of glucose. There were quantitative variations from the pattern in both groups of patients. It is suggested that at least 2 factors are responsible

the characteristic sharp rise and fall in
blood glucose level. The most important
ctor is the accelerated gastric evacuation and
id intestinal absorption of ingested glucose;
resultant portal hyperglycemia acts as a
ent stimulus for insulin release by the islet
ls of the pancreas. A rapid descent of blood
ar is a consequence of the resultant hyper-
sulinism. The cases of medically-treated duo-
al ulcer that exhibited this characteristic
tern (quantitatively to a much lesser degree)
ld be attributed to gastric hyperperistalsis
pled with rapid evacuation. Autonomic stimula-
on consequent upon rapid intestinal distention
proposed as a second factor in the cause of
poglycemia, possibly by way of increased glyco-
esis and islet stimulation.

43 RESULTS OF NO-LOOP GASTRECTOMY FOR
DUODENAL ULCER. (E.) Taylor, H. and
G. A. Eadie. Brit. Med. J. 1(5531):15-18, 1967.

llow-up data are presented on 336 "no-loop"
strectomy operations for duodenal ulcer performed
er a 20-yr. period. Of 18 deaths occurring, the
use in 3 was unknown; in the remaining 15,
ath was unrelated to peptic ulcer or the opera-
on. More than half the cases were observed
er 10 yr. and none less than 3.5 yr. All but
of 336 patients avoided discomfort after meals
moderate dietary restriction. There were no
ses of recurrent ulceration or ulcer-type
spepsia. When mobilization of the stomach was
stricted to the separation of the fundus from
e spleen, but leaving the gastrophrenic liga-
nt intact, earlier cases of regurgitation fol-
wing meals ceased and no further cases of bile
miting occurred. Of the 336 patients, 313
ssed 1 or 2 formed firm stools per day or were
nstipated, 20 reported loose stools on occa-
on, 3 reported diarrhea. Three patients showed
eatorrhea, 18 gained wt., 89 lost wt., and 229
mained at the same wt. Of the 76 patients
inically considered to be anemic, all responded
therapy. The absence of obstructive sequelae
the cases was taken to support the view that
en they occur a "loop" is the obstructive
gent. It is suggested that a less-extensive
esection of the stomach would produce less dis-
rbance of function with good control or re-
rrent ulceration and diarrhea.

044 D-XYLOSE TEST IN GASTRECTOMIZED PATIENTS.
(Rum.) Strat, C. (2nd Med. Clin., Iasi,
umania), N. Popescu and E. Popescu. Med. Intern.
Bucur.) 18(10):1163-1168, 1966.

ntestinal absorption was investigated in 26
astrectomized patients (Reichel-Polya operation).
ith one exception (post-traumatic rupture of the
tomach), the patients had been suffering from
astroduodenal ulcer. The subjects comprised
6 men (aged 28-58 yr.) and 10 women (36-58 yr.),
tudied 15 mo.-13 yr. after operation. In 12
atients, the degree of postoperative malnutrition (underweight) was mild (-3 kg); in 9, it was moderate (-8 kg); and in one, severe (-17 kg). The control group consisted of 20 healthy subjects (12 men aged 22-48 yr. and 8 women aged 19-45 yr.). The av. urinary pentose excretion (provoked pentosuria) was 5.8 g (range: 4.3-7.9 g). In 58.8%, urinary D-xylose excretion was normal; in 42%, it was reduced. Provoked hypercarotenemia levels were low normal in 49% (28-76 μg, as against 116 μg in controls). In 10 of 11 patients with abnormal D-xylose values, the following clinical symptoms were noted: jejunitis, accelerated intestinal transit, diarrhea, and (in one case) severe steatorrhea. It is concluded that the D-xylose test, in conjunction with other methods of investigation (radiologic, biologic, clinical), is a useful approach in the study of intestinal absorption.

6045 X-RAY FINDINGS AFTER PARTIAL GASTRECTOMY: A SERIAL STUDY IN MAN. (E.) Lehtinen, E. (U. Central Hosp., Turku, Finland) and M. Linna. Radiol. Clin. (Basel) 35(4):239-246, 1966.

Postgastrectomy changes of the gastric stump were evaluated in 16 patients subjected to Billroth II procedures. Roentgenographic assessment of the patient's condition was initiated during the sixth to tenth postoperative wk. with examination thereafter repeated at 3-6 wk. intervals. Radiographic technics employed during this serial study included ordinary plain roentgen films, image-amplification with television monitoring, use of a Philips "single-shot" camera and occasional cineradiography. At 6-10 days postoperatively, the usual picture included dilatation of the residual stump with a markedly edematous and irregular mucosal pattern. Swelling of the stoma was most pronounced at the opening of the efferent loop resulting in considerable impairment to the movement of contrast media, even in supine position. In addition, large quantities of secretions were observed in the gastric stump. Although no peristalsis was noted in the stump postoperatively, normal jejunal peristalsis was observed from the start of surgery. Gross distortion of the stomal region was observed occasionally. Mucosal patterns returned to normal in approx. 6 wk. Deformities at the mouth of the stoma gradually disappeared during this same period thus allowing passage of contrast media, almost always in the afferent loop antiperistaltically. Some filling defects persisted for long periods (9 yr. postoperatively in one patient); however, no functional abnormality was caused. Contrast media eventually passed into the efferent loop.

6046 AMINO ACID COMPOSITION OF THE BLOOD SERUM PROTEINS IN STOMACH CANCER PATIENTS. (Rus.) Savran, V. R. (Med. Inst., Lvov, USSR). Vop. Onkol. 12(10):30-35, 1966.

The amino acid composition of total serum protein of 105 patients suffering from stomach cancer was analyzed by paper chromatography and compared with that of sera of healthy individuals. The sera collected from patients exhibited dysproteinemia (increased proportion of α_1- and α_2-globulins and decreased level of albumins), as revealed by electrophoresis in agar gel. The cysteine and lysine contents of serum proteins of patients were, on the av., lower by 25.4 in 59 of 80 patients and 20.3% in 68 of 80 patients, resp., than those of normal sera, the decrease being more pronounced with increasing severity of the disease. Significant differences were not observed in the content of other amino acids. The decrease of cysteine and lysine content of serum proteins is not specific for stomach cancer as a similar phenomenon was observed also in ulcer patients.

6047 CARCINOMA OF STOMACH: EVALUATION OF INDIVIDUAL AND COMBINED DIAGNOSTIC ACCURACY OF RADIOLOGY, CYTOLOGY AND GASTROPHOTOGRAPHY. (E.) Blendis, L. M. (King's Coll. Hosp., London), J. O. W. Beilby, J. P. Wilson, M. J. Cole and G. D. Hadley. Brit. Med. J. 1(5541):656-659, 1967.

A total of 100 consecutive cases were investigated for cancer of the stomach by radiology (Ba meal), gastrophotography and exfoliative cytology. Of 20 patients with malignancy, a correct diagnosis was afforded by Ba meal in 18, gastrocamera in 18 and exfoliative cytology in 14; of 20 malignancies, 19 were detected by at least 1 of the 3 methods. For 80 with nonmalignant conditions, a correct diagnosis was given by Ba meal in 65, gastrocamera in 52 and exfoliative cytology in 67. The overall accuracy for each of the 3 methods was 83% with Ba meal, 70% with gastrocamera and 81% with exfoliative cytology. The latter method gave the only correct diagnosis in 4 patients with a false suspicion of malignancy. The management of 21 of the 100 patients was definitely affected by the combined technic.

6048 ENVIRONMENT AND HEREDITY FACTORS IN CARCINOMA OF THE STOMACH. (E.) Maddock, C. R. (Caernarvonshire & Anglesey Gen. Hosp., Bangor, N. Wales). Brit. J. Cancer 20(4): 660-669, 1966.

Factors related to the etiology of stomach cancer are reviewed, especially genetic influences in that region of Britain (North Wales) where stomach cancer mortality is the highest. Data obtained from the hospital records of 240 residents of Caernarvonshire and Anglesey who died with a well-founded diagnosis of stomach cancer between 1952-1958 showed no unexpected features with respect to symptomatology, sex distribution and gastric acidity. There was a deficiency of juxtapyloric cancer and an excess of lesser curvature and gastric body carcinomas, compared with findings elsewhere in Britain and Europe. Blood group determinations of 124 stomach carcinoma patients did not reveal the expected increase of blood Group A and deficit of blood Group 0 compared with healthy controls in the 2 counties; the usual association was reversed. The incidence of pernicious anemia in the populations at ris to it was not significantly different in Angles an island of high stomach cancer mortality and in the Isle of Man, an island of av. stomach cancer mortality. The 4 atypical features of gastric carcinoma in Anglesey and Caernarvonshi (unique blood group distribution, unrelated pernicious anemia incidence, unusual distribution site of origin of the tumors within the stomach and the high proportion of elderly cases) all conflicted with principles of hereditary influence in the disease. These peculiarities are probably the result of specific environment and exogenous factors powerful enough to obliterate evidence of the usual genetic factors; such a hypothesis is in accordance with previou findings of a gastric carcinoma-soil relationship in this area.

6049 CHEMOTHERAPY IN CANCER OF THE STOMACH. (E.) Wilken, B. J. (U. Edinburgh, Scotland) and J. W. W. Thomson. Brit. J. Surg. 53(10):904-906, 1966.

A total of 56 patients (27 men, 29 women) with stomach cancer were placed into groups accordin to the initial procedure of treatment carried out: Group 1, laparotomy (biopsy only, tumor irremovable), 33 patients; Group 2, bypass (tumor irremovable), 9 patients; and Group 3, resection (palliative; viable tumor left unresected), 14 patients. Patients were then giv a course of double antimitotic therapy: N-desacetylthiocolchicine (20 mg/day for 5-7 days; i.v.) and methotrexate (2.5 mg twice/day for 5-7 days; p.o.). Thereafter treatment was on an outpatient basis with 20-30 mg of N-desacety thiocolchicine once or twice a wk. and methotrexate, 5 mg/day, reduced after 4-6 wk. to 2.5 mg/day, in most cases. Of 47 patients who had an adequate course of chemotherapy, 31 were in Group 1, 7 in Group 2 and 9 in Group 3. Of 9 who failed to achieve an adequate course, 4 developed severe bone-marrow depression, hemorrhage or infection; 3 others died of their disease or intercurrent infection, but there were no significant toxic effects attributable to the drugs. Of the 47 patients, 25 showed objective improvement (6 of whom had an initial bypass), 3 had subjective improvement, 13 had no effect, 3 were made worse and in 3 results were too early to assess. A total of 15 of 47 were subjected to a second-look procedure (9 in Group 1, 1 in Group 2 and 5 in Group 3); survival time of this group was 3-22 mo. (1 patient is alive and well for 15 mo. at the tim of report). In 5 cases it was possible to resect a tumor which had previously been assessed as irremovable.

6050 GASTRIC DIVERTICULUM. (E.) Meeroff, M. (Gastroent. Serv., Buenos Aires,

entina), J. R. Maciel Gollán and J. C. Meeroff.
r. J. Gastroent. 47(3):189-203, 1967.

clinical and radiological features of gastric
verticulum are described. A total of 30 cases
4%; 19 of the patients were male) of this
ity were encountered out of a total of 7,500
iologic examinations of the stomach. Common
es of occurrence were juxtacardiac in 24 (80%),
tapyloric in 3 (10%), posterior wall in 2
66%) and greater curvature of the stomach in 1
33%). Coexistence of gastric diverticula with
verticula in other sites occurred in 8 cases
.6%); these included colonic diverticula in 3
0%), duodenal diverticula in 3 (10%), esophageal
verticula in 1 (3.3%) and gallbladder diverticula
1 (3.3%). In 50% of the patients the diagnosis
gastric diverticulum was unsuspected on clinical
ounds; in most, an associated lesion was re-
onsible for the symptoms. In one-third of the
tients, gastric diverticula alone were responsi-
e for symptoms: 6 with nonspecific abdominal
in, 3 with flatulent dyspepsia and 1 with hema-
mesis. Of 11 patients in whom duodenal ulcer
existed, 7 had typical ulcer symptoms, 2 had
gue symptoms and 2 were asymptomatic. Three
existed with cholelithiasis, all asymptomatic.
summary, the clinical picture included peptic
cer syndrome in 6, nonspecific abdominal pain
13, flatulent dyspepsia in 6, massive upper
strointestinal hemorrhage in 2 and lack of
mptoms in 3. In 1 case, gastric diverticulum
s first visualized at endoscopy. Medical treat-
nt of gastric diverticulum is preferred to sur-
ry; it consists of a soft diet, antispasmodics
d topical medication (bismuth and belladonna),
stric lavage and postural drainage. Preliminary
diology determines the site of the diverticulum
d the optimum position of the patient to pro-
te its emptying. Surgery is justified 1) when
equate medical treatment has failed and the pa-
ent complains of symptoms that cannot be as-
ibed to any other condition, and 2) when com-
ications have occurred and there is a risk that
ey may recur despite adequate medical treatment.

051 NEGATIVE RESPIRATORY WAVES IN STOMACH.
(E.) Geisel, A. (Michael Reese Hosp.,
hicago, Ill.), T. Arai, A. Doi, N. C. Jefferson
nd H. Necheles. Amer. J. Gastroent. 47(3):204-
08, 1967.

ale and female mongrel dogs starved for 12 hr.
ere anesthetized with pentobarbital. A bundle
f open-tip plastic tubes was passed through the
outh and openings of the tubes positioned in the
sophagus and in various segments of the stomach.
seven-tube unit was used for most studies,
penings were 5 cm apart and were made radiopaque
y inclusion of a small piece of metal. In dogs
ith Komarov esophageal fistulae, introduction of
he tubes was done without anesthesia and record-
ng was done with the dog lying or standing.
ositions of the tubes were checked repeatedly
y fluoroscopy. Each tube was perfused with
water through a T-tube, pressure changes were recorded by appropriate transducers. In 36% of 210 observations negative respiratory pressure waves were recorded in the stomach (150 normal anesthetized dogs and 60 dogs with fistulas). The reversals persisted for 1-10 min. in 26% of the cases noted, 10-60 min. in 37% and 60 or more min. in 37%. In the other 64% of the experiments there was no reversal of positive respiratory excursions in the stomach and during the entire experiment there were negative waves in the esophagus and positive waves in the stomach. Doubt is cast on the acceptability of pressure reversal as a tube passes from the esophagus into the stomach as an indication of the correct position of a tube in the stomach.

6052 INTRAGASTRIC PHOTOGRAPHY: GASTROCAMERA WITH FIBERSCOPE. (E.) Hara, Y. (Niigata Cancer Ctr., Japan), Y. Tobita, H. Tsunoda, K. Sugiyama, M. Arakawa, F. J. Ansfield and J. R. Hoon. Arch. Surg. (Chicago) 94(3):337-343, 1967.

A new device for diagnosis of stomach lesions, the gastrocamera in combination with a fibroscope, is described. This instrument was used on 1,000 patients without mishap. It is of greatest use in those cases where a doubtful gastric situation is presented by a nondiagnostic X-ray film or an equivocal gastrocamera examination. It may be useful in experimental medicine where the gastric phase of medication is of importance. It was successfully used in aged patients, in gravely ill patients and in those with lesions obscured by other diagnostic means. The superiority of a camera within the stomach (the gastrocamera) over instruments which photograph through a fiberscope bundle is emphasized.

6053 INTRINSIC-FACTOR ANTIBODY IN THE SALIVA OF A PATIENT WITH PERNICIOUS ANEMIA. (E.) Carmel, R. (Mt. Sinai Hosp., New York City) and V. Herbert. Lancet 1(7481):80-81, 1967.

Using a complex of ^{57}Co-labeled vitamin B_{12} intrinsic factor and ammonium sulfate precipitation methods, collected saliva samples were assayed for precipitable antibody to intrinsic factor in 3 patients with adult-type pernicious anemia. Demonstration that this antibody was primarily type IgA was indicated in 1 patient by its precipitation with anti-IgA. This same patient had precipitable antibody to intrinsic factor in both her gastric juice (primarily type IgG) and serum as well as a "blocking" antibody in the serum. Precipitable and "blocking" antibody to intrinsic factor were determined in both the gastric juice and serum of a second patient in whom no salivary antibody was found. A third patient showed only precipitable antibody to intrinsic factor only in gastric juice samples, with no "blocking" antibody in evidence from either serum or gastric samples.

The first patient in this series was considered a non-secretor, whereas the last two evaluated were secretors. The question as to whether the precipitable antibody in gastric juice represents, at least in part, an artefact is an open one due to both the addition of pooled normal gastric juice to each unknown sample and the technic of presaturating reagents with non-radioactive vitamin B_{12} both of which favor the artefact hypothesis. Neutralization of intrinsic factor may accelerate the genesis of frank vitamin-B_{12} deficiency in patients with already-reduced intrinsic factor secretion.

CLINICAL AND PATHOLOGICAL ASPECTS OF
PRIMARY CANCER OF THE SMALL INTESTINE.
) Busch, W. (Kaiser Franz Josef Hosp.,
a, Austria) and E. Wodak. Z. Gastroent.
315-323, 1966.

linical aspects of 832 cases of cancer of
ejunum and ileum, reported in the literature
1824, are reviewed and one case of carcinoma
e ileum under the care of the authors is con-
ed in detail. Of the 832 cases 497 (62%)
in the jejunum and 305 (38%) in the ileum.
precise localization occurred in 268 in-
es, 185 in the jejunum, 23 at the duodeno-
al flexure, 121 in the upper, 25 in the mid-
and 16 in the lower third of the jejunum;
ses were in the ileum, 7 in the upper, 18 in
iddle, and 58 in the lower third. Thus the
lence was greatest in the upper jejunum, next
est in the lower ileum and least in the upper
of the ileum. The overall incidence of
r in the small intestine was quite small; in
than 65,000 autopsies only 16 cancers were
overed. Among 428 cases reported in the
rature 117 patients (53.3%) were in the 40-59
age bracket. Among 647 cases, adenocarcinoma
rred in 603 (93.2%); solid carcinoma in 21
%); scirrhous tumors, 14 (2.2%); gelatinous
inomas, 7 (1.1%); other carcinomas, 2 (0.3%).
intestinal cancers form metastases relatively
in the regional lymph nodes and peritoneum;
ant metastases are seldom seen. The prognosis
arcinoid tumors of the intestine is poor al-
gh long-term healing is reported in the
rature after early resection. The authors
rt in detail a personal case of a solid poly-
hic cell carcinoma about 5 cm thick occurring
he lower ileum 25 cm above the ileocolic
ncter which was not diagnosed until autopsy.

INTESTINAL DECOMPRESSION. (E.)
Tinckler, L. F. Singapore Med. J.
:211-215, 1966.

istorical review of the technic used in
ative decompression of the distended,
ructed intestine is presented, together with
description of a new device designed to im-
e this operation. The device has an 8 mm
eter, a length of 180 cm and is made of trans-
nt vinyl NT/13 shore hardness 80; it possesses
umpet proximal end and bears a plastic bobbin
ts distal end. The tube has a terminal open-
and a lateral port just proximal to the
in. This new device can effectively decom-
s the distended obstructed small intestine
ng operation with minimal trauma to the in-
ine, and it can be left in situ for continued
operative treatment. Decompression of the
l intestine using this tubing is described
detail.

) FUNCTIONAL ASPECTS OF THE SMALL INTES-
TINE IN THE AGED. (It.) Rosa, L.
(U. Bologna, Italy), P. Vannini, L. Gandolfi and
A. Manaresi. Riv. Gastroent. 17(6):385-394, 1965.

The functional state of lipid absorption in the small intestine was studied in 24 aged patients with no clinical or laboratory evidence of digestive tract disturbances, and comparison was made with 15 normal subjects (age 16-35 yr.). Group 1 included 7 patients between the ages of 60-70 yr.; Group 2 included 12 between 71-80; Group 3 included 5 between 81-88 yr. old. Av. values for Groups 1, 2, 3, and controls were as follows: 4.7, 6.1, 9.4, and 3.6 g/24 hr., resp. (oleic acid test); 9.8, 11.4, 15.8, and 8.1% in 3 days, resp. (^{131}I-labeled oleic acid test); 5.9, 9.0, 12.1, and 3.3 g/24 hr., resp. (triolein test); 7.1, 12.6, 14.6, and 7.2% in 3 days, resp. (^{131}I-labeled triolein test); 5.9, 5.7, 4.8, and 6.3 g/urine 5 hr., resp. (xylose load test). Results indicate progressive impairment of intestinal lipid absorption with increasing age, and notable alteration of carbohydrate absorption only in patients over 80 yr. old.

6111 IRON CONTENT OF THE INTESTINAL MUCOSA
AS OBTAINED BY ORAL BIOPSY ACCORDING
TO THE CROSBY METHOD IN HEMOSIDEROSIS AND HEMOCHROMATOSIS. (It.) Astaldi, G. (Tortona Hosp.,
Tortona, Italy), G. Meardi and T. Lisino.
Minerva Gastroent. 12(2):57-58, 1966.

Determination of the Fe content of the intestinal mucosa by the Perls (Prussian blue) test in samples obtained by the Crosby oral biopsy method in 20 healthy subjects (after an 18-hr. fast) revealed no hemosiderin in the epithelial cells of the duodenum or jejunum, nor in the tunica propria of the duodenum. Fe pigment was, however, found in the tunica propria of many of the jejunal villi, especially in the form of granules in the cytoplasm of macrophages localized in the apical region of the villi. In 10 patients with post-transfusional hemosiderosis, no pigment was found in the epithelial cells of the duodenum or jejunum, whereas macrophages containing hemosiderin were present in the tunica propria of both the duodenum and jejunum. In the patient with hemochromatosis, 10% of the villi contained hemosiderin granules in their epithelial lining; 40-50% of the villi contained macrophages with hemosiderin granules in their tunica propria, but these were widely distributed and not limited to the apex. In the patient with hemochromatosis, no macrophages were found crossing the epithelium or beyond it, indicating that their function here regards Fe transport rather than elimination.

6112 INTESTINAL PROTEIN LOSS IN PATIENTS
WITH RHEUMATOID ARTHRITIS. (It.)
Marano, R. (U. Bari, Italy), G. Pastore and O.
Schiraldi. Boll. Soc. Ital. Biol. Sper. 42(14):
871-873, 1966.

Intestinal protein loss was assessed by fecal radioactivity determination in 5 female patients with rheumatoid arthritis 10 days after i.v. inj. of ^{51}Cr-labeled albumin (100 μc). Tests were conducted outside of the period of cortisone treatment. Marked increase in the fecal elimination of ^{51}Cr was observed in 3 of 5 patients, indicating abnormal intestinal protein loss. The authors conclude that amyloid transformation as a cause of protein loss is a rarely observed phenomenon and that the intestinal protein loss observed in these patients is more likely due to diffuse lympho-plasmacellular infiltration of the intestinal mucosa, a condition which can provoke reduced permeability of the intestinal wall to plasma proteins.

6113 β-GALACTOSIDASE ACTIVITY OF THE JEJUNUM AND ILEUM OF SUCKLING RATS. COMPARISON OF ACTIVITIES OF β-GALACTOSIDASE AT DIFFERENT CONCENTRATION OF SUBSTRATES (o-NITROPHENYL-β-D-GALACTOSIDE AND LACTOSE) AT DIFFERENT pH. (E.) Koldovský, O. (Inst. Physiol., Prague), A. Heringová and V. Jirsová. Biol. Neonat. 10(5-6): 241-253, 1966.

The β-galactosidase activity of homogenates of the jejunum, ileum and isolated microvilli fraction of suckling rats (14-days-old) and weanling rats (24-days-old) was studied; lactose and o-nitrophenyl-β-galactoside were used as substrates at different conc. and different pH. Quantitative and qualitative differences disappeared during weaning. It was also shown that the microvilli fraction contains a β-galactosidase activity with a high affinity for lactose; 80% of the total homogenate activity of the jejunum, estimated at pH 6.0 using lactose as a substrate, was found in this fraction.

6114 PATHOGENESIS OF JEJUNAL MUCOSAL ALTERATIONS: SYNECHIA FORMATION. (E.) Schenk, E. A. (U. Rochester Sch. Med., N. Y.), I. M. Samloff and F. A. Klipstein. Amer. J. Path. 50(3):523-531, 1967.

More than 500 jejunal biopsy specimens from 139 patients (celiac disease, 19; tropical sprue, 24; protein malnutrition, 3; anemia, 7; regional enteritis, 5; postgastrectomy, 4; agammaglobulinemia, 3; other gastrointestinal disorders including diarrhea, 69; and normal, 5) were examined. Most biopsy specimens, except those which were flat or convoluted, revealed a mixed pattern; leaf-shaped villi were usually found admixed with normal finger-shaped villi, and villus ridges often occurred in the presence of leaf-shaped villi. All tissues obtained from patients with untreated celiac disease had a flat or almost flat mucosa, while those from patients with tropical sprue had considerable variation in the degree of villus abnormality; 4 had a normal villus pattern, 10 showed villus ridges, 6 were convoluted and 5 were completely flat. Of biopsy samples from patients with diagnoses other than tropical
sprue or celiac disease, 22 were normal, 16 ha
leaf-shaped villi, 47 had ridges, and 9 had a
convoluted pattern. Two specimens were com-
pletely flat; 1 was from a patient with an Fe-
deficiency anemia and 1 from a patient with
protein malnutrition. Specimens that demonstr
a normal villus pattern, ridges, leaves or con
volutions usually were serially sectioned; 2
normal tissues, 7 with a leaf-shaped pattern
13 of those ridged had microscopic evidence o
what was interpreted as villus fusion or syne
formation; this process occurred most often n
tips of the villi, but it was also seen at an
level along the villus wall. Sizes of the sy
iae were variable; some consisted of no more
than 2 or 3 adjacent epithelial cells while o
included a major portion of 2 adjacent villi.
jejunal mucosal abnormalities described most
likely occur as a result of inflammatory adhe
between villi. Complete loss of a villous pa
with a flat mucosa may result from 1) further
adhesions between adjacent ridges, or 2) an i
flammatory cell infiltration and edema within
lamina propria of the villi. These results d
onstrate that villus synechiae are commonly e
countered in jejunal biopsy specimens that sh
minimal other abnormalities.

6115 INFLUENCE OF INTESTINAL CONTENT ON
RADIATION LESIONS OF THE SMALL INTE
(E.) Hiatt, N. (Cedars-Sinai Med. Ctr., Los
Angeles, Calif.) and N. E. Warner. Proc. Soc
Exp. Biol. Med. 124(3):937-939, 1967.

Five dogs were prepared with Thiry-Vella fist
each consisting of a 15-cm segment of mid-jej
2 dogs were irradiated with 1,000 r to the ab
and 3 with 1,500 r. After radiation, only th
epithelial changes were the same in the isola
loop and in the small intestine in continuity
The mucosa in fistulous segments were relativ
well-preserved; in contrast, the rest of the
small intestine had typical changes that foll
exposure to radiation. These included mucosa
erosions with hemorrhage, reduction in overal
mucosal thickness, attenuated or absent villi
an inflamed, congested lamina propria and gre
distention of mucosal glands, with mucus stas
These results suggest that intestinal content
exacerbates radiation injury of the small int
tine, just as it aggravates lesions induced b
a radiomimetic drug. It is suggested that le
ening of the isolated segment and shortening
the intestine in continuity will significantl
improve postirradiation survival.

6116 CHEMOPROPHYLAXIS WITH PENICILLIN.
PREVENTION OF BACTERIAL GANGRENE IN
ISCHEMIC INTESTINE. (E.) Cole, W. R. (4960
Audubon Ave., St. Louis, Mo.), E. D. Maley, P
George and H. R. Bernard. Arch. Surg. (Chica
94(2):182-183, 1967.

The mesenteric artery was ligated in 22 dogs
distal to the first jejunal branch; 11 select

random were given 1 x 10^6 U of penicillin G
500 ml of lactated Ringer's soln. before
erial ligation and another 1 x 10^6 U of peni-
lin G 24 hr. after operation. The same vol.
lactated Ringer's soln. was given to controls
hout adding penicillin. All control dogs died
hin 72 hr. and all showed necrosis of the in-
tine varying from a few cm to total necrosis
the entire segment supplied by the occluded
ery. No necrosis was found in the intestines
animals treated with penicillin, and only 1 of
se animals expired within 72 hr. These results
onstrate the effectiveness of antimicrobial
rapy in the prevention of bacterial gangrene
ischemic intestine in the dog. It is suggested
t chemoprophylaxis should be considered as an
unct to good surgical technic during the per-
mance of surgery on ischemic organs.

7 SMALL-BOWEL EPITHELIAL MIGRATION DURING
A GENERALIZED NONENTERIC INFECTION IN
RAT. (E.) Shambaugh, G. E. (Walter Reed
y Med. Ctr., Fort Detrick, Md.), D. S. MacNair
W. R. Beisel. Amer. J. Dig. Dis. 12(4):403-
, 1967.

ponse of small intestinal epithelial migration
ing a nonenteric infection was investigated in
lt male Dunning-Fischer rats. There was a
sustained increase in crypt mitotic activity
hr. after a s.c. inoculation of Diplococcus
umonia, type I-A5; this was followed by a
ilar nonsustained increase in small intestine
thelial-cell migration 8 hr. afterward. Neither
structure of the villi nor the appearance of
epithelial cells was altered during the in-
tion.

8 FETAL DEVELOPMENT OF NONSPECIFIC
ESTERASES AND ALKALINE PHOSPHATASES
IVITIES IN THE SMALL INTESTINE OF MAN. (E.)
ichová, H. (Charles U., Prague), O. Koldovský,
Uher, J. Kraml, A. Heringová and V. Jirsová.
l. Neonat. 10(5-6):281-287, 1966.

activity of the soluble nonspecific esterase
bstrate β-naphthyl acetate) in the proximal
distal third of the human small intestine did
change between 7 and 22 wk. after conception;
ivity was always higher in the ileum. Electro-
resis revealed the presence of 1 anodic and 2
hodic fractions, both of which moved together
h the "slow moving gamma globulins". Soluble
aline phosphatase activity increased steadily
the jejunum; in the ileum an increase was first
erved between 7 and 11 wk. after conception,
later such activity decreased. No proximo-
tal difference was found in the age group of
-10.5 fetal wk.; in a single 22-wk.-old fetus,
re was relatively low alkaline phosphatase
ivity in the ileum and high activity in the
unum. In older fetuses (11-18 wk.-old), ileal
ivity was several times higher than in the
nger age group and also significantly higher
an in the jejunum.

6119 THE PATHOLOGY OF PROLIFERATIVE ILEITIS OF THE GOLDEN SYRIAN HAMSTER. (E.) Boothe, A. D. (Nat. Animal Dis. Lab., Ames, Iowa) and N. F. Cheville. Path. Vet. (Basel) 4(1):31-44, 1967.

Lesions of an acute and chronic ileitis were studied in golden Syrian hamsters (92 animals; 6-12 wk. old). Morbidity and mortality rates were 25-60% and 90%, resp. The initial lesion was epithelial hyperplasia of the ileal mucosa; severe inflammatory changes in the ileum and adjacent structures were secondary. No etiologic agent was isolated, and the disease was not neoplastic. Proteus and Pseudomonas spp., usually together, were the organisms found most frequently in the intestine; Escherichia coli or Aerobacter aerogenes were rarely isolated, but when present, they were not from the same animals from which Proteus or Pseudomonas spp. were isolated. No Salmonella spp. were isolated. E. coli was occasionally demonstrated in heart blood. Inoculation p.o. with E. coli produced a watery diarrhea and enteritis, but not lesions of proliferative ileitis. Animals inoculated with intestinal contents or macerated ileal wall did not develop ileitis. Approx. 10% of fecal flotation preparations contained eggs of Ascaris spp. and of Hymenolepis nana, or both. No coccidia were found.

5   SPONTANEOUS PEPTIC ULCERS IN MICE.
(E.) Williams, A. W. (U. Otago,
edin, New Zealand), J. B. Howei, B. J. Helyer
L. O. Simpson. Aust. J. Exp. Biol. Med. Sci.
1):105-108, 1967.

ups of NZB mice, totaling 1039 in all, were
mined after death at various ages. This
ain was previously reported to have a moderate
idence of chronic peptic ulcers. The mice
e killed by ether, the stomach contents taken
pH measurements, and the stomach and duodenum
ed. After fixation was complete the mucosa
inspected for lesions. Approx. 130 males
143 females were "terminally killed" because
y were very sick; the rest were killed in
onological sequence. In healthy mice peptic
ers first appeared between 2 and 4 mo. of
, the incidence rose to a max. of 80% be-
en 24 and 26 mo. In terminally killed mice
incidence rose more steeply reaching 100%
the 26th mo. The majority of ulcers were
uated at or immediately distal to the pyloric
g, although occasional ulcers occurred in the
mach. The lesions were usually oval or round
ging from 1-2 mm in diameter. Most ulcers
wed replacement of the full thickness of the
ceral wall by fibrovascular or fibrous
nective tissue, infiltrated by lymphocytes
plasma cells, as well as polymorphonuclear
kocytes and histiocytes. Mucosal plaques in
duodenum were common. Plaques occurred
lier than ulcers and reached a max. of 75% at
11 mo. and dropped to 20% by the 26th mo.
re was no correlation between ulcers and
tric juice pH, or any of the blood tests.
etiology and pathogenesis of the ulcers is
yet uncertain.

6   RIBOFLAVIN DEFICIENCY AND GASTRIC
ULCER PRODUCTION IN THE RAT: A
CEDURE FOR THE STUDY OF SUSCEPTIBILITY TO
ESS-INDUCED GASTRIC ULCERS. (E.) Kim, Y. S.
Nebraska Coll. Med., Omaha) and J. P.
booy. J. Nutr. 91(2):183-188, 1967.

nling female Wistar rats were maintained
er standard conditions and fed a diet
icient in riboflavin. All rats used were
st made deficient; those used as normals
e fed a riboflavin-supplemented diet. After
dying several combinations a stress of a
r. period of rocking (cage rocked 160
les/min., excursion 2.5 cm) on each of 5
cessive days was selected as a stress. This
cedure was earlier found to produce multiple
ers in the glandular portion of the stomach
all deficient rats tested. Rats fed a
plemented diet for 12 days showed no ulcers
er 6 days of the rocking procedure. Two
mal studies were carried out, ad libitum
eding and paired feeding. In the ad libitum
rats all of the deficient animals showed
cers after 5 days of the stress procedure.
None of the rats fed the supplemented diet had ulcers. In the second study 3 rats in the deficient group and 2 in the supplemented group died. In the deficient group 14 of 15 rats showed extensive ulceration. In the control group 2 of 15 were found to have small lesions. The lesions seen were described by pathologists as typical ulcers, similar to small unperforated gastric ulcers in humans.

6147   THE IMPORTANCE OF THE "NEUROGENIC" FACTOR IN THE GENESIS OF THE SHAY GASTRIC ULCER. (It.) Loscalzo, B. (U. Naples, Italy) and F. Di Mezza. Minerva Med. 57(75): 3028-3032, 1966.

Gastric ulcers were induced by the Shay method in 65 rats of both sexes (av. wt. 233.2 g) fasted for 36 hr. but fed water ad libitum before surgical treatment. Group 1 (39 rats) received 1 ml/100 g of a 10% gum arabic soln. i.p. after surgery; Group 2 (26 rats) received an i.p. inj. of meprobamate-barbiturate after the 10% gum arabic. The ulcers which developed in animals of Group 1 were more frequent and more lethal than those in rats of Group 2. The av. mortality was 28.2% in Group 1 as compared to 0% in Group 2; the av. ulcer index was 38.9 in animals of Group 1 as compared to 12.57 in animals of Group 2. Results indicate that a neurogenic factor plays an important part in the mechanism of development of Shay ulcers as shown by the partial protection afforded by the admin. of CNS depressant drugs.

6148   GASTRIC ULCERS IN SWINE. I. EFFECT OF DIETARY PROTEIN, DIETARY FAT AND VITAMIN E ON ULCER DEVELOPMENT. (E.) Nafstad, I. (Vet. Coll., Oslo, Norway). Path. Vet. (Basel) 4(1):1-14, 1967.

The effects of different protein and fat levels, and the supplement of vitamins B_1 and E and the amino acids lysine, methionine and tryptophan on development of gastric ulcers in pigs were studied in 3 experiments involving 72 pigs. Addition of vitamin B_1, amino acids and the feeding of low fat rations did not change the number of stomach lesions observed, but a modifying effect of vitamin E on ulcer development was noted. Feeding of low protein diets resulted in no increase in the total number of stomach lesions, but appeared to increase their severity.

6149   GASTRIC ULCERS IN SWINE. II. EFFECTS OF HIGH FAT DIETS AND VITAMIN E ON ULCER DEVELOPMENT. (E.) Nafstad, I. (Vet. Coll., Oslo, Norway) and S. Tollersrud. Path. Vet. (Basel) 4(1):15-22, 1967.

Feeding pigs diets with large amounts of unsaturated fatty acids either in fresh or oxidized condition was strongly ulcerogenic. The addition of amino acids or Se to the diet, or an increase of dietary protein did not change the number of lesions. Vitamin E had a slight, but not significant, degree of protection against gastric lesions. An increased severity of the lesions when vitamin E was omitted from the ulcerogenic diet was more obvious. A serious vitamin E deficiency might cause a physiologic lack of vitamin A, which may have been related to gastric ulceration, but it has been shown that addition of high levels of vitamin A to swine rations does not prevent ulceration; therefore a possible action of the tocopherols (vitamin E) in ulcerogenesis cannot be sought in their interrelation with vitamin A. The mode of action of vitamin E in preventing gastric lesions is discussed.

6150 GASTRIC ULCERS IN SWINE. III. EFFECTS OF DIFFERENT PROTEINS AND FATS ON THEIR DEVELOPMENT. (E.) Nafstad, I. (Vet. Coll., Oslo, Norway), S. Tollersrud and B. Baustad. Path. Vet. (Basel) 4(1):23-30, 1967.

A report is presented in which the effects of saturated dietary fats and different sources of protein on gastric ulcers in pigs is described. Diets were tested in which hydrogenated coconut oil and soybean meal replaced cod-liver oil and casein of a previous ulcerogenic diet. Feeding of saturated instead of unsaturated dietary fats caused a reduction in the severity of gastric lesions. No ulcers, but some epithelial changes, occurred in the stomachs when casein was partially replaced with soybean meal, or by using the latter as the only source of protein (at a level of 27%). However, all pigs on a ration containing 36% soybean meal had normal stomachs. These results are compared with results from other studies.

6151 PRODUCTION OF DUODENAL ULCERS BY EXOGENOUS GASTRIN. AN EXPERIMENTAL MODEL. (E.) Gobbel, W. G., Jr. (VA Hosp., Nashville, Tenn.) and R. B. Adkins. Amer. J. Surg. 113(2):183-187, 1967.

Gastrin was extracted from hog antral mucosa using Gillespie and Grossman's method. To obtain a sustained release of gastrin the extracted material was lyophilized and incorporated into an aqueous gelatin suspension. A similar histamine-free fundic mucosa extract was prepared as a control. S.c. inj. of the gastrin-gel mixture into Heidenhain pouch dogs increased pouch acid up to 24 hr. compared to an 9 hr. effect of aqueous soln. Of 35 guinea pigs receiving gastrin in 16% gelatin (gastrin dose equal to 35 g of hog antral mucosa/kg) every 12 hr. for 14 days duodenal ulcer developed in 26 animals within 14 days. All ulcers were duodenal and developed within 1 cm of the gastroduodenal junction. Of the 26 animals in which ulcers developed, perforation with peritonitis and death developed in 24. A bleeding ulcer developed in one animal and a deep penetrating ulcer developed in one animal Guinea pigs receiving 16% gelatin only, aqueou gastrin only, or an extract of hog gastric fundic mucosa failed to develop ulcers. The method is considered to offer a new technic fo the experimental production of duodenal ulcers

6152 COMPARATIVE EFFECTS OF ATROPINE AND OCTYLATROPINIUM ON RESTRAINT ULCERS IN RATS AND ALBINO MICE. (Fr.) Mercier, J. (Fac. Med. Pharm., Marseille, France) and S. Lumbroso. Therapie 21(6):1537-1542, 1966.

In rats undergoing 24 hr. of restraint and mic restrained for 7 hr. after a 24-hr. fast (both at 20°C), the ulcer incidence was 70% an 75%, resp. Rats were treated with parasympath colytic agents in 2 doses (at the beginning of restraint and 12 hr. later); mice received 1 dose at the beginning of restraint. In rats, atropine sulfate or atropine octobromide (10-40 mg/kg) caused dose-dependent protection against stress ulcer (30-100%); in mice, atrop conferred 35% and 55% protection at 2 and 4 mg/kg, resp., but had no effect at 1 mg/kg. I both rats and mice, N-octylatropinium Br was 5-6 times less active (50% protection at eithe 20 or 24 mg/kg in mice; 10% or 50% protection at 80 or 120 mg/kg, resp., in rats). Carbacho induced gastric hypersecretion was inhibited by atropine better than N-octylatropinium, the difference being a factor of 7.5. It is concluded that the anti-ulcer effects of N-octylatropinium Br result from inhibition of gastric secretion.

6153 EFFECT OF ENVIRONMENTAL TEMPERATURE ON THE PRODUCTION OF RESTRAINT ULCEF IN THE RAT. (Fr.) Buchel, L. (Inst. Pharmacc Fac. Med., Paris) and D. Gallaire. C. R. Soc. Biol. (Paris) 160(10):1817-1820, 1966.

In fasting (24 hr.) rats restrained for 2.5 h at environmental temperatures of 24-38°C, the max. ulcer incidence was 35%. The frequency and severity of the ulcers increased as the environmental temperature was reduced (incide 95% at 14°C). After 1.5 hr. of restraint, the ulcer incidence was also temperature-dependen (from 15% at 32°C to 75% at 14°C). Unrestrai rats did not develop ulcers. In non-fasting rats, the ulcer incidence was also temperature dependent, but the frequency was lower at comparable temperatures (at 14° and 1.5 and 2. hr. of restraint, 45% and 62%, resp.). The CNS-mediated decrease in body temperature during restraint was important but not the only factor in ulcer production. In fasting rats undergoing 1.5 hr. of restraint at 14°C, the ulcer incidence in controls was 60% and body temperature fell 3.2°C. Nonhypnotic doses of phenobarbital (100 mg/kg) and hypnotic doses chloral hydrate (300 mg/kg) exaggerated the f rectal temperature (decreases of 5.5 and 9.3°C, sp.) but also reduced the ulcer incidence 5% and 30%, resp.).

54 GASTRIC HISTIDINE DECARBOXYLASE LEVELS AND EXPERIMENTAL ULCERS IN THE RAT.

r.) Schwartz, J. C. (Fac. Pharm., Paris), Y. hen and G. Valette. Biochem. Pharmacol. (12):2122-2124, 1966.

rats treated with ulcerogenic doses of enylbutazone (100 mg/kg; ulcer incidence 9 of) or serotonin (8 mg/kg; incidence 8 of 10) ter a 24-hr. fast, or undergoing restraint for hr. after a 14-hr. fast (incidence 12 of 13), omach histidine decarboxylase levels 4 hr. ter treatment (in mμM/3 hr.) were 1.72, 1.33 d 2.06, resp., a significant increase from ntrol values (0.79). Ulcerogenic doses of serpine (8 mg/kg; incidence 7 of 7), however, d not increase histidine decarboxylase tivity. Phenylbutazone did not induce ulcers stimulate this enzyme in rats fed ad libitum.

55 PHARMACODYNAMIC AND CLINICAL STUDIES OF A NEW ANTISEROTONIN, 8599 RP, IN IE TREATMENT OF DUODENAL ULCER.

(Fr.) Bereni, Gaz. Hop. (Paris) 139(6):259-264, 1967.

animal experiments, 3-(dimethylamino-2'-opyl)-10-phenothiazine dimethyl sulfamide, in ne methanesulfonate form (8599 RP; Migristene; -20-mg capsules, 50-mg suppositories or 10-mg lixir) was 3 times more powerful than pro-ethazine as a serotonin antagonist, with equal superior antihistamine activity; its anti-erotonin activity was 2 times less than that of ethysergide. Significant protection against lcers was noted in guinea pigs treated with istamine and the Shay serotonin ulcer in rats. n 30 patients with duodenal ulcer (23) or with astritis, duodenitis or gastroduodenitis (7), igristene elixir (60 mg in 2 days; 3 patients) r suppositories (27 patients) suppressed gastric ecretion in 10 of 11 patients with hyper-hlorhydria (the single exception had pyloric tenosis with an ulcer); it had no effect in 4 atients with hypochlorhydria and gave variable esults in patients with normochlorhydria. The esponses were independent of the presence or bsence of ulcers. The elixir (30 mg/day for 20 ays) was admin. to 23 patients with recent (5) r established (18) duodenal ulcers (2 with yloric stenosis, 2 with histories of perforation). ood-to-excellent responses (pain relief within -10 days, usually within 3 days) were seen in 7 patients, including all cases of established lcer without stenosis. Moderate responses were oted in 3 patients, all with recent ulcers. ne patient with an acute ulcer of recent origin nd the 2 patients with pyloric stenosis failed o respond; the 2 latter patients underwent urgery within a short time. No other treatment as given during this period. No side effects ere noted at this dose level.

6156 ULCERS WITH BOTH GASTRIC AND DUODENAL LOCATIONS. ANATOMO-CLINICAL AND THERAPEUTIC STUDY OF 15 PERSONAL CASES.

(Fr.) Edelmann, G. (Coll. Med., Paris Hosp., France) and J. Brénot. Arch. Franc. Mal. Appar. Dig. 55(11):1015-1032, 1966.

Double ulceration was noted in 6% (15) of 236 patients undergoing surgery. The duodenal ulcer preceded the gastric ulcer (sometimes by several yr., even by over 10 yr.) in 14 cases. The gastric ulcers were found in the lesser curvature in all 15 patients and multiple gastric ulcers were noted in 2 patients. All duodenal ulcers were single and of bulbar location, but their evolution was almost always much less severe than that of the gastric ulcers; in fact, 13 of them were completely healed. Pyloric stenosis by scar tissue was noted in 8 patients; in 7 cases it resulted from the duodenal ulcer. Acute hemorrhage was present in 3 patients; 2 patients had histories of perforation. Malignant degeneration of the gastric ulcer was noted in 1 patient (mucinous adenocarcinoma). Double gastric and duodenal ulceration could not be diagnosed on the basis of secretion tests; the possibility that the gastric ulcer was a secondary trophic lesion arising from static gastritis was considered but no conclusions could be drawn. The authors believe that conservative treatment is of doubtful value in this syndrome; 14 of their patients underwent subtotal gastrectomy (removing both ulcer sites simultaneously) with good results.

6157 ANTRUM-PYLORUS MALFUNCTIONS IN ULCERS OF DUODENUM AND STOMACH.

(Ger.) Hegglin, J., A. Sumser and M. Allgöwer. Gastroenterologia (Basel) 106(3):180-192, 1966.

The so-called benign pyloric hypertrophy of the adult may in fact be the result of a dysfunction of the canalis egestorius, i.e., the distal antrum and pylorus; with stasis of these regions a gastric or duodenal ulcer is to be expected; if the stasis is overcome by the force of contractions from above, a gastric ulcer can be anticipated; if, however, hyperacidity is marked, a duodenal ulcer develops. Typical signs of these events are: (1) Pylorus hypertrophy in the X-ray plates, increased length and stenosis of the pyloric canal with extensions of stenosis into the antrum, depression of the base of the bulbus, changes in peristalsis, and gastric retention without apparent cause such as carcinoma, polyps, or compression by external tumors. (2) Gross examination at operation: thickening of the wall of the distal antrum and the pylorus; narrowing of the canal; peristalsis ceases upon mechanical stimulation. (3) The gastric content after a 12-hr. fast is increased by more than 40 ml. Corroboration was secured by biopsy from the anterior wall of the distal antrum and the pylorus in 56 cases. The histology revealed: (1) Thickening of pyloric smooth muscle only. The circular muscle of the pylorus was 4 times the thickness of the longitudinal muscle caused by both hypertrophy and hyperplasia; or, (2) Fibromuscular changes occurred in pylorus and antrum with the circular muscle surrounded and infiltrated as well as invasion of the submucosa by fibrous connective tissue; or, (3) Fibrous connective tissue invasion without any change in number or size of muscle fibers in the circular or longitudinal layers. The histology of the antropyloric regions of the stomach in 16 subjects with normal digestive tracts was studied as control material; these subjects were young adults who died by accident. The antrum-pylorus biopsies among 22 patients operated upon for gastric ulcer showed 10 to have muscular involvement only and 12 a fibromuscular change. Among 23 patients with duodenal ulcer, 1 had a muscular change only, 10 had fibromuscular change, 9 submucosal fibrosis only and 3 showed no pathological conditions in these regions. All gastric ulcers were marked by muscular or fibromuscular hypertrophy, but submucosal fibrosis was absent. In 19 of 23 cases, duodenal ulcers showed submucosal fibrosis. Controls were all negative for muscular changes and only occasional evidence of fibrosis was observed.

6158 PHYSIOPATHOLOGICAL ASPECTS OF THE ADRENAL CORTEX IN GASTRIC AND DUODENAL ULCER DISEASE. (Rum.) Savulescu, V. (Med. Clin., Adult Hosp., "Tudor Vladimirescu" Region, Rumania), I. Andronache, I. Stefan, A. Gancevici, S. Stancescu, S. Tincu, E. Iliescu and P. Teodorescu. Med. Intern. (Bucur.) 18(10): 1189-1197, 1966.

During the past 2 yr., adrenocortical function was investigated in 86 patients, 15 with gastric, and 71 with duodenal, ulcer. The age of those with gastric ulcer ranged from 20-65 yr. (av. 39 yr.), with a duration of the disease ranging from a few mo. to 16 yr. (av. 2 yr., 4 mo.) and a final, acute period of 3-4 wk. Those with duodenal ulcer ranged in age from 20-60 yr. (av. 35 yr.), with illness for 1 mo.-17 yr. (av. 4 yr., 6 mo.), and acute symptoms for 7 days to 4 mo. (av. 6 wk.). The diagnosis was based on the clinical, radiologic, and gastric secretion findings (tested with alcohol, insulin, and histamine-loading). Androgenic steroid production was tested by determining 24-hr. urinary 17-ketosteroid excretion in basal conditions and after stimulation with ACTH and with insulin. Androgen function varied under all 3 conditions: in a small number of patients (15%), it was normal; in a large number (esp. in patients with duodenal ulcer), it was enhanced (in 38%); and in the majority (47%), and especially in those with gastric ulcer, it was reduced. ACTH stimulation caused marked eosinopenia in 92%, and insulin stimulation did so in 100%. These reactions indicate adrenal hyperactivity (of central, hypothalamo-pituitary origin) in active gastroduodenal ulcer disease; in the quiescent phase, this tendency tends to decline or disappear.

6159 NOCTURNAL SECRETION STUDIES IN DUODENAL ULCER. (E.) Raghavan, P. (Seth G. S. Med. Coll., Bombay), V. N. Acharya and B. D. Pimparkar. Indian J. Med. Res. 55(2): 109-118, 1967.

Nocturnal gastric secretion, obtained by continuous aspiration for a period of 8 hr. between 10 P.M. and 6 A.M., was studied in 130 cases of radiologically-proven duodenal ulcers. The av. secretory vol. was 366.8 ml (range, 100-1030 ml), the mean total acidity (titrated to pH 7.4) was 31.8±28.0 mEq/liter and the av. pH was 2.07. An augmented histamine test was also performed 2-3 days before studying nocturnal gastric secretion. Study of nocturnal secretion before and after vagotomy showed a consistent decrease in vol. and acidity after the operation. There was no significant correlation between nocturnal secretion and age, height, body wt., hemoglobin and serum proteins. A significant correlation was obtained between basal and nocturnal secretion and between max. histamine response and nocturnal secretion. It was found that basal secretion provides as much information as the 8-hr. nocturnal secretion in cases of duodenal ulcer. The high basal secretion in these duodenal ulcer subjects and the significant correlation between the nocturnal and basal secretion may indicate the influence of vagal overactivity in the production of hypersecretion in these subjects.

6160 POSSIBILITIES OF USING THE MAXIMAL HISTAMINE SECRETION TEST IN PATIENTS WITH DUODENAL ULCER. (It.) De La Pierre, M. (U. Turin, Italy), S. Gabasio and G. Bruno. Minerva Med. 57(73):2940-2945, 1966.

In 54 male patients (av. age 43 yr.) with clinically and radiologically confirmed duodenal ulcer who were subjected to the Kay test of max. histamine secretion, both basal as well as histamine-stimulated HCl secretion were significantly increased (6.82 mEq/hr. and 31.48 mEq/hr at 1 hr., resp.) with respect to controls. Gastric secretion levels after histamine were higher than the av. (controls) + 1 sigma in 36 of 54 (67%) patients and higher than the av. (controls) + 2 sigma in 24 of 54 (44%) patients. Basal gastric secretion decreased with age, while histamine-induced secretion was lower in patients under 30 yr. old than in those over 50. Marked individual variability in gastric secretion levels was observed both before and after the test. Results indicate that the Kay test has little diagnostic value in patients whose HCl secretion vol. is less than 39.9 mEq/hr. On the other hand, the test is of value in preoperative studies, inasmuch as the choice between gastric resection and vagotomy can depend upon the patient's gastric secretion levels before and after the test.

161 CHRONIC PULMONARY EMPHYSEMA AND GASTRO-DUODENAL ULCER. (It.) Salonna, L.
J. Bari, Italy), A. Racanelli and R. Bassi.
rogr. Med. (Napoli) 22(15):583-589, 1966.

adiological studies of the stomach and uodenum were conducted in 60 patients (56 men nd 4 women; age 20-76 years) with chronic ulmonary emphysema (47 compensated and 13 right ecompensated). All patients complained of yspeptic disturbances and in most cases chronic ypertrophic gastritis with frequent duodenitis ere observed radiologically. In 17 of 60 atients (30%), gastric (8 patients) or duodenal 9) ulcers were present. Autopsy revealed lcerative lesions in 4 patients. Four patients ad been subjected to resection for previous astric ulcer. Of the 17 patients with ulcers, 0 were compensated and 7 right decompensated; ll had third-degree respiratory insufficiency. f 17 patients with 5,000,000 or more RBC, 8 48%) had gastric or duodenal ulcers and 9 had ypertrophic gastritis or gastroduodenitis. he importance of high RBC, smoking, and hyper-erotoninemia as causal factors are discussed.

162 TREATMENT OF PEPTIC ULCER BY HIGH DOSAGE OF PROPANTHELINE BROMIDE. (E.)
oberts, D. M. (British Milit. Hosp., Munster, lest Germany). Amer. J. Gastroent. 47(2):
24-133, 1967.

f 60 patients (17-46 yr. old) with peptic ulcer, had ulcers which were pyloric and 58 which ere duodenal in origin. These were divided nto 2 groups: Group 1, 29 patients who were reated with as much as 360 mg/day of ropantheline bromide, and Group 2, 31 (controls) atients treated by standard methods. There as no significant difference in either the ymptomatic or radiological response between the groups, and there was a surprising lack of correlation between the radiological and symptomatic response. Side-effects developed in 3 of 29 patients treated with high dosage of propantheline bromide; these included xerostomia (21), cycloplegia (12), epistaxis (5), constipation (4) and hesitancy of micturition (1). It is concluded that propantheline bromide is no better than conventional methods in treating peptic ulcer, and that the concept of "sustained gastric inactivity" introduced by Barowsky et al. is of no value as a method of treating duodenal ulcers in young men.

6163 FOUR CHOLERIFORM SYNDROMES AFTER 550 VAGOTOMIES. (Fr.) Picard, J. M.
(Cent. Reg. Hosp., Nancy, France), A. Larcan, M.
Calamai and E. Polo. Anesth. Analg. (Paris)
23(4):847-856, 1966.

Four patients with duodenal ulcers complicated by perforation (2) or pyloric stenosis (2) and poor nutritional status developed choleriform syndromes due to staphylococci 2-6 days after vagotomy with gastroenterostomy. Broad-spectrum antibiotics were admin. to these patients immediately after surgery (penicillin + Terramycin in 1 case; unspecified in 3 cases). The syndrome was attributed to an upset of the microbial balance in favor of resistant staphylococci and intestinal stasis secondary to vagotomy. Electrolyte imbalance was treated by replacement therapy; at least 2 patients were also treated with antibiotics (erythromycin + spiramycin, or staphylomycin + pyostacin) on the basis of in vitro sensitivity tests. One patient failed to respond and died within about 1 wk.; the other 3 patients responded promptly, although diarrhea persisted for over 2 wk. in 1 case and a subphrenic abscess later developed in another patient.

6164 VAGOTOMY IN THE TREATMENT OF POST-ANASTOMOTIC PEPTIC ULCER. (CASE STUDY). (It.) Ferrara, L. (U. Turin, Italy) and A. Gaetini. Minerva Gastroent. 12(2):
59-63, 1966.

From 1948-65 vagotomy was performed only 20 times among 1,000 patients subjected to gastric resection for gastroduodenal ulcer. Results with resection and gastroenterostomy alone had been very good, and vagotomy was limited to patients with recurrent ulcer and those with simple stomitis. In 12 patients, vagotomy alone (9 supra- and 3 subdiaphragmatic) was performed; results were excellent in 7 (58%), good in 2 (17%), moderate in 2 (17%), while 1 (8%) patient died. Of 8 patients subjected to vagotomy and a second gastric resection, results were excellent in 2 (25%), good in 4 (50%), moderate in 1 (12.5%), while 1 (12.5%) patient died. One patient had been subjected to vagotomy and gastroenterostomy at another hospital 10 yr. previously without benefit; since no recurrence was evident, simple antrectomy was performed; 4 yr. later the patient was in good general condition. Selective vagotomies were never performed. Of 44 other patients with recurrent ulcer who were subjected to degastroenterostomy only, results were excellent in 22 (50%), good in 13 (30%), moderate in 7 (11%), while 2 (4%) patients died.

6165 COMPLETENESS OF GASTRIC VAGOTOMY BY THE SELECTIVE TECHNIC. (E.)
Griffith, C. A. (U. Washington Sch. Med., Seattle). Amer. J. Dig. Dis. 12(4):333-350, 1967.

In a series of 64 patients (51 men and 13 women, 19-64 yr. of age) who were treated for duodenal ulcer by bilateral selective gastric vagotomy together with pyloroplasty, completeness of gastric vagotomy was evaluated. Preoperative (12-hr. collections in 55 patients) and postoperative (85 tests were obtained early at 7 days and late from 6 mo.-5 yr.

postoperatively) basal gastric secretions were obtained and analyzed for vol., presence of bile and blood, pH, and the number of mEq of free and total acid per unit time. Postoperative insulin tests were conducted in 54 patients (68 tests). Hypersecretion was confirmed in 41 patients preoperatively. Postoperatively, 20 of 58 patients secreted free acid with 5 secreting more than 1.5 mEq/hr. free acid. One of these 5 patients showed no free acid in early testing, but converted to free acid in late testing. With respect to postoperative insulin testing, all 46 patients with tests unvitiated by duodenal reflux and/or inadequate hypoglycemia showed a clinical response to insulin (fall of true glucose to or below 45 mg% in 41 patients, to 30-50 mg% in 3 patients and the last 2 patients had a severe insulin reaction preventing blood sampling). Basing a positive response on an increase of at least 0.5 mEq in the first 2 hr. after inj., there were 40 negative, 5 positive and 1 questionable responses. One unique case showed pink basal and post-insulin specimens of gastric juice (pigment unknown) and that he was a true hypersecretor, after a seemingly complete vagotomy. It is concluded that preservation of hepatic and celiac-vagi by selective technic provides consistently complete or adequate vagotomy of the stomach in man based on positive encirclement and transsection of all gastric vagal branches.

6166 SELECTIVE GASTRIC VAGOTOMY TECHNIC AND PRIMARY RESULTS.

(E.) Amdrup, E. (Municipal Hosp., Copenhagen, Denmark), T. Clemmesen and J. Andreassen. Amer. J. Dig. Dis. 12(4):351-355, 1967.

A technically simple method for performing gastric vagotomy is described. The principle of this procedure is to omit free dissection of the individual nerve fibers and, instead, to divide the lesser omentum transversely from a point opposite the angular notch in toward the lesser curvature of the stomach; then, working from below upward, the lesser omentum is dissected free from the lesser curvature and from the distal 4 cm of the esophagus. A total of 74 patients were operated on using this method. An insulin test was carried out on 61 patients; it was negative in 54 cases, early positive in one and late positive in 6.

6167 OPERATIVE COMPLICATIONS OF GASTRODUODENAL ULCERS.

(E.) Széll, K. (Markusovszky Hosp., Szombathely, Hungary). Acta Chir. Acad. Sci. Hung. 7(4):417-424, 1966.

Of 2323 gastrectomies (1685 Billroth I, 590 Billroth II and 48 other types) performed in the treatment of gastroduodenal ulcer, complications resulted in 412 cases (19.5%). No observable difference between Billroth I and II procedures was evidenced with respect to both mortality rate (1.2%) and the incidence of postoperative complications, though the incidence of such complications was higher and more varied for Billroth II procedures, probably reflecting its threefold greater application. Most of the early complications were of a respiratory nature (76 patients, 12.9%; 211 patients, 12.5% for Billroth I and II procedures, resp.), while all other complications were less than previously described. These included for Billroth I and II operations, resp., wound infection and suppuration (0.85% and 1.1%), intestinal paralysis (0.85% and 0.54%), and suture insufficiency (0.51% and 0.59%), pleuritis (in Billroth II only at 0.65%), pulmonary infarction (0.34% and 0.53%), pneumonia (0.34% and 0.30%), phlebothrombosis (0.34% and 0.25%), hematemesis (0.34% and 0.18%), thrombophlebitis (0.17% and 0.25%), cerebrovascular disorders (0.34% and 0.12%). Other significant complications involved the cardiovascular (0.34% in Billroth I only) and urogenital systems. Obstruction and disorders of the intestinal tract accounted for 0.65% of complications (0.13% fatal).

6168 CONSERVATIVE SURGERY FOR BLEEDING PEPTIC ULCER.

(E.) Carruthers, R. K. (Gen. Infirm., Leeds, England), G. R. Giles, C. G. Clark and J. C. Goligher. Brit. Med. J. 1(5532):80-82, 1967.

Experience over 5 yr. with 112 patients treated by emergency operation for bleeding peptic ulcer was reviewed. Hemorrhage resulted from acute erosions in 13 patients, duodenal ulcer in 79, and gastric ulcer in 20 (in 6 with an associated duodenal ulcer). Radical surgery (usually Polya gastrectomy) was performed 55 times. The conservative operations, usually vagotomy and pyloroplasty with suture of the bleeding vessel were performed in 57 patients. Considering the survival rate for duodenal ulcer, gastric ulcer and erosions, conservative surgery had lower mortality with the exception of patients with erosions. Recurrent bleeding was observed in 8 patients after conservative surgery (4 required a second operation) and in 6 after radical surgery. A further operation was necessary in 11 patients treated by gastric resection. It is concluded that conservative surgery seems to be satisfactory in the treatment of bleeding duodenal ulcer, and warrants consideration in the treatment of gastric ulcer. The place of conservative surgery in the treatment of erosions remains uncertain.

6169 STUDIES RELATED TO THE PATHOGENESIS OF CURLING'S ULCER.

(E.) O'Neill, J. A., Jr. (Brooke Army Med. Ctr., Fort Sam Houston, Texas), B. A. Pruitt, Jr., J. A. Moncrief and W. E. Switzer. J. Trauma 7(2):275-287, 1967.

Clinical experience with 193 cases of Curling's ulcer seen over a 13 yr. period were reviewed.

he yearly incidence varied widely but av. 12.5%.
t was considered that the "true" percentage
as probably higher. The majority of the
atients presented with bleeding without
ssociated symptoms. In 42 of 193 patients
here were no symptoms whatever, and the ulcers
ere discovered at autopsy. The majority of the
lcers were gastric and usually multiple. All
lcers appeared to be acute with minimal
nflammatory reaction. The majority of the
lcers had stainable bacterial or fungus
rganisms on the surface of the crater. Sepsis
controlled in a large fraction of the popula-
ion by topical sulfonamide) shock, hemocon-
entration and absolute hyperacidity (only 4 of
4 patients had in excess of 25 mEq/12 hr.) were
ot considered adequate explanations for the
tiology of Curling's ulcer. It is suggested
he ulcers may be related to decreased mucosal
esistance due to a decreased rate of gastric
ucus production. Surgical treatment resulted
n survival in 45% of 20 cases of Curling's
lcer, with massive hemorrhage. It is suggested
hat surgery should routinely be considered for
hese patients when conservative treatment fails.

170 DISTRIBUTION OF GASTRIC AND DUODENAL ULCER IN AFRICA. REVIEW OF LITERATURE
F THE LAST 40 YEARS (1927-1966). (Ger.)

195 CLINICAL STUDY OF CROHN'S ILEO-COLITIS.
(Fr.) Vantrappen, G. (Saint Raphael
., Louvain, Belgium), E. Lens, J. Vandenbroucke,
. Bodart and C. Dive. Arch. Franc. Mal. Appar.
ig. 55(12):1129-1148, 1966.

n 29 men and 15 women with Crohn's disease
only 12 were over 30 yr. old at onset), the
rincipal symptoms were diarrhea (55%), epigas-
ric or right iliac fossa pain (32% in each
ase) and isolated, external fistulas (13.5%);
rthralgia sometimes preceded the onset of these
ymptoms. Melena was infrequent and usually not
bundant; leukocytosis and wt. loss indicated
xacerbation of the disease. Internal fistulas
ere present in 21 cases (48%) and were most
requent in the presence of segmental involve-
ent; 5 of the 14 patients in this group showed
ouble fistulas. The right hemicolon was
nvolved in 43% (19 cases) and the entire colon
n 25% (11 cases). No fulminant hemorrhage,
oxic megacolon, overt perforation or malignant
ransformation was noted in this group.
orticosteroids (unspecified) were admin. to 34
atients (77%), all with segmental or total
involvement (65% had fistulas, but this was not
considered an absolute indication for cortico-
steroid therapy); 14 of these patients later
underwent surgery (the most effective procedure
was resection of the lesions), 8 of them (57%)
after over 1 yr. of improvement without corticosteroid treatment. Of the 20 patients treated with corticosteroids without surgery, 8 (40%) remained in good condition after the end of corticosteroid therapy and 9 (45%) were well and on corticosteroids at the time of report; 2 patients failed to respond to corticosteroids. Surgery was performed in 17 patients in all; 2 died in the postoperative period, 11 patients responded well (8 required no steroid therapy) and 5 patients had recurrent disease at the time of report.

6198 EXPERIENCE WITH REGIONAL ENTERITIS AT TWO HOSPITALS. (E.) Hodosh, S. (Wadsworth Hosp., Los Angeles, Calif.) and E. Passaro, Jr. Amer. Surg. 33(3):234-237, 1967.

6199 ACUTE PERFORATION OF THE SMALL INTESTINE IN REGIONAL ENTERITIS. (E.) Sewell, J. H. (Fort Worth Clin., Tex.). Amer. J. Gastroent. 47(2):148-152, 1967.

6200 ABSORPTION AND NET METABOLISM OF D-FRUCTOSE, L-SORBOSE AND SORBITOL IN HEREDITARY FRUCTOSE INTOLERANCE AND IN HEALTHY INFANTS. (Ger.) Beyreiss, K. (Karl Marx U. Leipzig, Germany), H. Willgerodt and H. Theile. Acta Biol. Med. German. 17(6):733-745, 1966.

Absorption and net metabolism of fructose, sorbose and sorbitol were compared in healthy infants and in a child with hereditary fructose intolerance. After admin. p.o., only 30-40% of the fructose was found in the peripheral blood of healthy control infants, whereas all of it was found in the peripheral blood of the child with hereditary fructose intolerance. This suggested the absence of phosphofructoaldolase and the lack of fructose metabolism in the intestinal mucosa. After p.o. admin. of sorbose, approx. 30% of it was found in the peripheral blood of both control infants and the child with hereditary fructose intolerance. Blood levels of glucose and fructose were similar after i.v. infusion of sorbitol or fructose in the infant with hereditary fructose intolerance. After p.o. admin. of sorbitol, blood glucose decreased in hereditary fructose intolerance in spite of small absorption of sorbitol. Net metabolism of fructose was not markedly decreased in hereditary fructose intolerance; however, fructose was metabolized with increased blood levels. The net metabolism of sorbose was markedly decreased. The results are discussed with regard to the mechanism of absorption of fructose.

6201 USE OF MEDIUM CHAIN TRIGLYCERIDES IN MALABSORPTION. (E.) Greenberger, N. J. (Ohio State U. Hosp., Columbus), R. D. Ruppert and M. Tzagournis. Ann. Intern. Med. 66(4):727-734, 1967.

Use of triglycerides containing medium chain fatty acids was studied in a group of 12 patients with malabsorption. Medium-chain triglyceride therapy produced a significant decrease in steatorrhea in 9 patients; in 6 of these there was a minimal but definite gain in wt. Severe, disabling diarrhea was improved in 6 patients. The most striking improvement occurred in 5 patients with regional enteritis; lesser degrees of improvement occurred in patients with Laennec's cirrhosis, carcinoma of the pancreas, scleroderma and pancreatic insufficiency. Two patients developed increased diarrhea and abdominal pain while receiving medium-chain triglyceride therapy. No significant change in blood glucose, plasma nonesterified fatty acid and serum insulin levels was observed in 10 normal subjects after ingestion of 30 ml of medium-chain triglyceride oil. It is concluded that medium-chain triglyceride therapy may be a valuable nutritional adjunct in patients with malabsorption.

6202 OSTEOPOROSIS, INTESTINAL LACTASE DEFICIENCY AND LOW DIETARY CALCIUM INTAKE. (E.) Birge, S. J., Jr. (Barnes Hosp., St. Louis, Mo.), H. T. Keutmann, P. Cuatrecasas and G. D. Whedon. New Eng. J. Med. 276(8): 445-448, 1967.

Normal results were obtained in a group of 10 patients with confirmed osteoporosis and 13 normal subjects given oral lactose tolerance tests, whereas decreased lactose absorption was indicated in a group of 9 osteoporosis patients. Accuracy of the test was confirmed by its use in determining jejunal enzyme levels in 11 subjects. Lactase deficiency was considered to be demonstrated when the percentage ratio of max. elevation in blood sugar, following lactose admin., to the max. elevation achieved by admin. of a mixture of 25 g glucose and 25 g galactose was less than 50%. All 9 patients were diagnosed as having primary lactase deficiency which was supported by normal findings with respect to serum proteins and carotene, xylose tolerance, stool fat and upper gastrointestinal roentgenograms. All lactase deficient patients related histories of long-standing milk intolerance (severe in 6 and mild in 3) along with lactose malabsorption and very low dietary milk and Ca intake (200±50 mg was the mean daily intake over approx. the preceding 10-yr. period). Attempts at induction of lactase activity in 5 deficient patients by lactose admin. (15 g/daily reduced to 7.5 g/day) were unsuccessful after a 3-mo. course of treatment. The positive correlation between primary lactase deficiency and osteoporosis may indicate a single biochemical form of the bone disease. It is suggested that voluntary Ca restriction to preclude any symptoms of lactose intolerance inaugurated by drinking milk may be a partial cau of osteoporosis in lactase-deficient patients.

6203 A LIGHT AND ELECTRON MICROSCOPIC STUDY OF SIGMOID COLONIC MUCOSA IN ADULT CELIAC DISEASE. (E.) Pittman, F. E. (U. Birmingham, England) and J. C. Pittman. Scand. J. Gastroent. 1(1):21-27, 1966.

Sigmoidoscopic and light microscopic examinations of sigmoid colonic mucosa of 4 untreated and 2 treated (treated with a gluten-free diet for periods of 6 mo. and 2 yr., resp.) patients with adult celiac disease were normal. When mucosa from the 4 untreated patients was studied under the electron microscope, abnormalities of the microvilli were seen, with collections of finely granular material, similar to apical cytoplasm, within the microvillous borders of principal cells and in the lumens of crypts; this material seemed to be exuded from microvilli. There were no ultrastructural abnormalities observed in the mucosa obtained from the patients after successful treatment with a gluten-free diet. Gliadin peptides, obtained by digestion with trypsin and pepsin, produced minimal microvillous changes when given as an enema to 1 patient who had been treated for 6 mo. with a gluten-free diet.

4 REGULATION OF INTESTINAL ALKALINE
PHOSPHATASE LEVELS IN THE RAT. ROLE
THE ADRENAL CORTEX. (E.) Watson, W. C.
y. Infirm., Glasgow, Scotland), E. S. Murray
M. D. Gardner. J. Clin. Path. 20(2):185-189,
7.

ateral adrenalectomy caused a reduction in
alkaline phosphatase conc. in the rat
le Wistar) intestine, which was not prevented
admin. of saline (1%); this effect was
evented by admin. of cortisone (2.5 mg
rtisone acetate). Admin. of ACTH (4 U/day x
s.c.) to normal rats produced a rise in
estinal alkaline phosphatase levels
sociated with a small increase in adrenal
and wt.; admin. of hydrocortisone (1 mg or 10
/day for 10 days; s.c.) produced large
creases in the enzyme, with doses (10 mg) that
used significant hypoplasia of the adrenal
ands. The significance of these results in
lation to mechanisms of fat absorption and the
eatment of steatorrhea is discussed.

05 SMALL INTESTINE STUDIES IN GIARDIASIS.
(E.) Cantor, D. (Nat. Inst. Health,
enos Aires, Argentina), L. Biempica, H.
ccalino and J. C. O'Donnell. Amer. J. Gastroent.
(2):134-141, 1967.

junal biopsies (along with X-ray and
boratory studies) were performed in 22
ildren (14 males and 8 females aged 18 mo.-
yr. of age) infested with Giardia lamblia and
whom chronic diarrhea was the main sign in an
tempt to establish a positive relationship, if
y, between this parasite and malabsorption.
l children were in good general health (1
tient with Cooley's anemia). Roentgenological
terations were nonuniform and included wide
men (6), thick folds (4), mucosal coarsening
), flocculation (1), segmentation (7),
ypermotility (6) and normal picture (6). Only
case showed an X-ray pattern consonant with
alabsorption syndrome. The fat balance test
measured by the Van de Kamer test) was normal
16 cases, slightly elevated in 4 cases and
ncreased markedly in just one case. Histologi-
al examination showed a nonspecific pattern
ith changes confined to the lamina propria and
ncluded congestion (mostly in the villi),
dema, and round cell and eosinophil infiltration.
dema frequently produced a mild and non-
eneralized clubbing of the villi and dissocia-
ion of glands. It is concluded that mal-
bsorption syndrome and giardiasis are distinct
athological conditions.

206 THE KINETICS OF INTESTINAL ABSORPTION
OF RADIOHIPPURAN IN CONTROL SUBJECTS
AND IN PATIENTS WITH INTESTINAL MALABSORPTION.
(E.) Turco, G. L. (U. Turin, Italy), P. De
Filippi and G. Segre. J. Nucl. Biol. Med.
10(2):52-57, 1966.

A mathematical model was described by which it was possible to calculate the kinetics of the passage of ^{131}I-hippuran from the human gastrointestinal tract into the blood. ^{131}I-hippuran, an essentially inert molecule, was considered to meet the requirements for a test substance for intestinal absorption studies. Nine normal subjects and 4 patients showing the malabsorption syndrome were studied. Blood and urine levels were determined after i.v. and p.o. admin. of ^{131}I-hippuran. After 25 μc was inj. i.v., blood was sampled and counted for radioactivity every 2-5 min. for 25-30 min. After 1 wk. each subject received 75 μc of radiohippuran by mouth. Following p.o. admin. blood was sampled and counted for 150 min. The data collected were fitted to a 4-compartment model using a digital computer, and values for transfer constants between venous compartments obtained. It was found that, in patients with malabsorption syndrome, the transfer constant representing the passage of the tracer across the intestinal wall was markedly affected, whereas the blood kinetics did not appreciably differ from those observed in the normals. The method is felt to have potential diagnostic value in malabsorption syndromes.

6207 DISACCHARIDASE ACTIVITIES IN MILK-SENSITIVE AND CELIAC PATIENTS. (E.) Lubos, M. C. (U. Saskatchewan, Canada), J. W. Gerrard and D. J. Buchan. J. Pediat. 70(3) (Pt. 1):325-331, 1967.

Fifty-six children were studied, 18 sensitive or intolerant of milk, 22 with celiac disease, and 16 with a variety of other conditions other than malabsorption. Peroral intestinal biopsy was carried out, an attempt being made to obtain the specimen near the ligament of Treitz. Oral lactose tolerance tests were performed in 13 milk-sensitive patients and in 5 celiac ones. Lactose (2 g/kg) was admin. and blood sugar determinations made periodically. All intestinal biopsies from the milk-sensitive group revealed normal histology. There was no difference in the mucosal disaccharidase activities of this group and the control group. A flat blood sugar curve was found in 6 of 13 patients following lactose challenge. Only 1 patient experienced diarrhea following admin. of lactose. Improvement in mucosal morphology was noted in 6 of the treated celiac patients; all treated patients showed significantly decreased disaccharidase activities compared to controls. Untreated celiac patients showed clearly marked villous atrophy; 5 of these 6 patients showed flat lactose tolerance curves. Disaccharidase activity was significantly below normal. It is concluded that lactose intolerance does not appear to be the primary cause of the diarrhea in milk-sensitive patients, since the disaccharidase activity of these children fell within normal limits. Reduced disaccharidase activity was noted in celiac patients, but no evidence of lactose intolerance was present.

6208 EFFECTS OF PROLONGED GLUTEN FEEDING IN HEALTHY SUBJECTS. I. SERUM LIPIDS AND FATTY ACID PATTERNS. (E.)

Gormican, A. (2015 Summit Ave., St. Paul, Minn.), M. A. Ohlson and M. Osborn. J. Amer. Diet. Ass. 50(2): 122-125, 1967.

Total serum lipids and serum fatty acids were determined in 2 healthy 33-yr.-old volunteer males maintained on a high-gluten diet in a metabolic ward for 5 mo. After a 1-wk. control period on a general diet, the subjects were placed on a metabolic diet designed to maintain normal constant wt. and to provide approx. 50% of the total daily protein intake in the form of gluten; the basic diet contained 2,600 calories provided by 126 g protein (including 51 g gluten in the form of desserts and breadstuffs), 270 g carbohydrate and 114 g fat. Fasting and post-test meal serums were analyzed; serum lipids were analyzed monthly for blood lipid patterns at 1, 3, 5 and 7 hr. after ingestion of fat tolerance meals. Gas-liquid chromatography was used for fatty acid analysis. Serum lipids increased after the test meal in both subjects during the study. Elevated serum lipids were sustained 7 hr. after the test meal as the study progressed. There was considerable variation in the serum saturated and unsaturated fatty acids. In 1 subject, there was a marked increase in serum palmitic acid, with a lesser relative increase in serum oleic acid. The percentage of oleic acid was measurably increased after a test meal containing triolein. As the experiment progressed, the monthly fat meal induced more intense and more prolonged lipemia.

6209 STUDIES ON PROPHYLAXIS OF COW'S MILK ALLERGY BY DIGESTIVE ENZYMES. (E.)

Gamo, I. (Osaka U. Med. Sch., Japan), H. Yabuuchi, M. Nishida, T. Ikeda, T. Ichihara and K. Toyoshima. Acta Paediat. Jap. [Overseas] 8(15):1-12, 1966.

Seven cases of breast-fed infants allergic to cow's milk are described. The patients were 1-4 mo. old, in whom the disease began with such symptoms as urticaria, eczema and diarrhea. Cow's milk allergy was diagnosed by the provocation test, and aggravation of symptoms occurred by drinking human milk after taking cow's milk. The passive cutaneous anaphylaxis reaction confirmed that cow's milk antigen is transmitted to human milk after consuming cow's milk; electrophoresis and chromatography showed that this antigen exists in both the protein and peptide fractions. The passive cutaneous anaphylaxis reaction was markedly weakened in human milk after taking digested cow's milk. These results suggest that the mother's intake of cow's milk should be noted when admin. treatment by removal of the antigen in infants who are allergic to cow's milk during the period when they are fed with human milk.

6210 NEUROLOGICAL DISORDERS ASSOCIATED WITH ADULT COELIAC DISEASE. (E.)

Cooke, W. T. (U. Birmingham, England) and W. T. Smith. Brain 89(4):683-722, 1966.

Neurological disturbances are reported along with clinical, laboratory and autopsy findings (9 of 16 patients) in 16 patients (11 men and 5 women, aged 26-68 yr.) with adult celiac disease, the duration of which varied between 5 mo.-9 yr. Clinical findings included symptoms affecting the legs especially sensory ataxia, less severe and common symptoms involving the arms (3 patients were unable to write legibly or manipulate buttons), peripheral neuritis, diminished muscle power, incoordination of legs, unconsciousness (6 patients), cerebellar dysfunction (3 patients). All patie showed flexor plantar reflexes (except for one showed an extensor reflex prior to death). Lab ratory findings included uniform steatorrhea, achlorhydria (3 patients), impaired ^{58}CoB$_{12}$ (3 9 patients tested), osteomalacia (5 patients), positive test for toxoplasmosis (3) and one patient manifested persistent high WBC count. Pathological alterations are detailed for the cerebral cortex, basal ganglia, hypothalamus, cerebellum, brain-stem, spinal cord, sensory ganglia and peripheral nerves. No amelioration neuropathy was associated with absence or admin of folic acid, vitamin B$_{12}$ or a gluten-free die At the time of the report, 9 patients have died with neuropathy being the primary cause in 4 patients and a significant contributing factor another 4 patients. One case died from a rapid progressive neuropathy 3 mo. after appearance o symptoms, while another died from a reticulosar of the small intestine. Six patients have mani ted steady improvement, with no change in neuro athy or disability after 1-7 yr.

6211 STUDIES ON THE INTESTINAL ABSORPTION OF ^{3}H-FOLIC ACID IN IDIOPATHIC SPRUE.

(Ger.) Kistler, H. J. (U. Zurich, Switzerland), J. R. Schmid, E. Pfenninger, U. P. Haemmerli and P. G. Frick. Gastroenterologia (Basel) 106(3):204-216, 1966.

The malabsorption syndrome of idiopathic sprue (1-40 yr. duration) was observed in 10 patients (4 men and 6 women, 38-75 yr. old), all having suffered from a macro-megalocytic anemia, which responded not only to vitamin B$_{12}$ but also to folic acid therapy. Folic acid deficiency is seldom seen in idiopathic sprue, whereas it is a prominent feature of tropical sprue. Of these 10 patients, 4 had a severe degree of malabsorption, 4 showed partial remission and 2 complete remission; 8 had received B$_{12}$ treatment for anemia; 3 were on a gluten-free diet and 2 on a low-gluten diet; there was no correlation between B$_{12}$ treatment or diet and the degree of malabsorption. No correlation was found in the tests on absorption of folic acid, the fecal fat conc., histological stage of intestinal mucosa, and B$_{12}$ conc. in the stool among other determinations. Thus, only 1 patient showed a slightly abnormal nount of B_{12} in the feces (9.1%; below 8% is rmal); 1 case in Stage 3 was normal in every espect, except for absorption of folic acid; nother patient, also in Stage 3, had greater nan normal absorption of folic acid. The ritiated folic acid was measured by its radioctivity. Although in general the absorption folic acid was less in the patients with prue (half the normal level) the plasma clearnce of folic acid introduced i.v. was much ore rapid than in normal individuals (twice as ast). The slowed rate of folic acid absorption ay have been due to decreased conc. of enzymes cting upon folic acid. Tests of disaccharide onc. in controls and in 8 patients with idioathic sprue showed that conc. of maltase, somaltase, saccharase and lactase were below ormal in 5,4,3, and 7 instances, resp. and in he low or very low normal ranges in 2,4,5, and instances, resp.; maltase and lactase were ach in av. normal range in 1 instance. It is uggested that patients with idiopathic sprue e treated with parenteral folic acid at an arly stage.

212 MALABSORPTION SYNDROME OBSERVED AFTER THE MASSIVE RESECTION OF THE SMALL NTESTINE. (Jap.) Matsumoto, S. (Hokkaido U. ed. Sch., Sapporo, Japan), T. Ito, S. Suzuki, . Iwazaki, A. Okuno, W. Nagano, K. Nakayama, N. hida and T. Haraguchi. Shonika Rinsho (Jap. J. ediat.) 20(1):77-91, 1967.

ne case is presented of a secondary malabsorpion syndrome in a 16-yr.-old male due to assive resection of the small intestine 11 yr. previously. The patient was in an automobile ccident at the age of 5. Due to rupture of the liver and damage to the small intestine, surgery was done to resect about two-thirds of the small intestine and to make a jejunum-descending colon anastomosis and blind loop of a part of the jejunum. Some symptoms indicating malnutrition, such as small body structure, edema, petechiae and anemia, gradually developed 5 yr. after the accident. They became severe after 10 yr. (RBC number 2.0 x 10^6). Absorption tests showed marked malabsorption, especially of K, Ca, phosphate, Mg, fats, fat-soluble vitamins and vitamin B_{12}. The admin. of these substances markedly improved the general condition.

6220 HIRSCHSPRUNG'S DISEASE--THE DUHAMEL MODIFICATION. (E.) Newbern, W. R. (130 Butler St., West Palm Beach, Fla.). Amer. J. Gastroent. 47(1):61-68, 1967.

Results of this modified surgical procedure (by which a new combined rectal ampulla with the posterior half composed of normal colon is created) in 4 children with Hirschsprung's disease is reported. A successful application of this modified procedure was carried out in a 10-mo.-old male infant in order to partially resect a prolapsed distal loop of a colostomy which had been performed at age 4 wk. Except for frequent soft stools, which became regular and formed after 3 mo., no postoperative complication was encountered. Adequate peristalsis was demonstrated in the rectal stoma. Another patient with aganglionic disease of the rectum and sigmoid, had the involved distal segment resected and the distal end of the left colon pulled through as a left colostomy. Two wk. later a right transverse colostomy was performed which was subsequently complicated by recurrent respiratory infections. A minor wound infection occurred in this case, but pelvic abscesses, evident peritonitis, fecal impaction or diarrhea did not occur. In 2 other infants with Hirshsprung's disease, Duhamel modification was completed without complication. In view of the excellent results achieved, along with the need of less pelvic dissection as well as less operative shock and maintenance of adequate peristalsis, the modified Duhamel procedure is recommended for the treatment of Hirschsprung's disease.

6221 DETRUSOR INHIBITION INDUCED FROM ANAL REGION IN MAN. (E.) Pompeius, R. (Sahlgrenska Hosp., Goteborg, Sweden). Acta Chir. Scand. 132(Suppl. 361):1-54, 1966.

Detrusor inhibition elicited by anal stimulation is supposedly due to an inhibitory reflex via the spinal cord. The present investigation comprises a study of the receptor mechanism and the afferent part of the reflex arc, a study of the level of the supposed spinal reflex and a study of the supraspinal influences upon the reflex in patients under general anesthesia and in patients with cerebral lesions. A brief summary of the anatomy and neurophysiology of the anal and lower genitourinary region is given. Material for this study included 76 patients (53 men, 23 women, with a mean age of 60 yr.) with various urological and neurological disorders. Cystometry (recording of the intravesical pressure changes) was used to study the effect of anal stimulation upon rhythmic detrusor activity and micturition contractions. Following local anesthesia of the anal and perianal skin (4 cases), anal mucosa (24) and of the internal anal sphincter (5), detrusor activity was still inhibited by anal stimulation in 4 of 4, 20 of 24 and 4 of 5, resp. When the external anal sphincter, lower part of the ana mucosa and the ano-perianal skin was anestheti (4 cases), no inhibition was recorded during anal stimulation (0 of 4). Inhibition of detrusor activity during anal stimulation was recorded in 7 of 10 observations in 9 patients with complete spinal cord transection. No inhibition was recorded by anal stimulation in 3 cases with an incomplete lesion of the conus medullaris or the cauda equina. An inhibition of detrusor activity was recorded in 3 of 4 patients who had bilateral total adrenalectomy. In 5 patients in whom the urinary bladder had been replaced with an isolated sigmoid segment, inhibition of its motor activity was noted in 4 during anal stimulation; no inhibition was recorded in 5 patients in whom the lower ileum had been used for the same purpose. In nearly all of 25 patients, touch and painful stimulation of the ano-perianal region had an inhibitory effect upon detrusor activity. In 4 patients in whom detrusor activity was inhibite by anal stimulation or painful stimulation of the anal skin, no inhibition was recorded when painful stimuli were applied to skin dermatomes outside the sacral region. Anal stimulation had an inhibitory effect upon detrusor activity in 7 of 8 patients with various cerebral lesion who had no bladder control. The same effect was found in 2 of 3 patients under hexobarbital anesthesia. Several conclusions were made on the basis of these results: 1) receptors for the anovesical inhibitory mechanism are located in that part of the anal region that is somatically innervated through the pudendal nerve; 2) detrusor inhibition induced by anal stimulation is due to a segmental reflex that traverses the sacral part of the spinal cord; no evidence was found for the sympathetic nervous system as a mediator of this reflex; and 3) the anovesical inhibitory reflex can be released in the neurologically healthy man without important facilitatory influences from supraspinal sources. The significance of the anovesical inhibitory reflex for urinary retention after surgery of the anal region and as a complication to acute anal disorders is discussed; it is suggested that the anovesical inhibitory reflex is partially responsible for this urinary retention. A similar mechanism is partly responsible for urinary retention after operations in the perineum and around the vulva. Measures to decrease the frequency of postoperative urinary retention after anoperianal surgery are also discussed.

6222 ABSORPTION AND SECRETION OF ELECTROLYTES AND WATER BY THE HUMAN COLON, WITH PARTICULAR REFERENCE TO BENIGN ADENOMA AND PAPILLOMA. (E.) Shields, R. (Welsh Nat. Sch. Med., Cardiff, Wales). Brit. J. Surg. 53(10): 893-897, 1966.

absorption and secretion of electrolytes water by the colon was studied in 13 males ng modified Tyrode's soln, which contained a (2 μC/liter soln.), ^{42}K (4 μC/liter soln.), (1% vol./vol.) and as a nonabsorbed erence substance, polyethylene glycol of ecular wt. 4,000 (1% wt./vol.). Five were ients with benign neoplastic disease of the ge intestinal mucosa: 2 with villous illoma of the rectum, 2 with multiple poly- is of the entire large intestine and the th patient was studied before and after the oval of polyps by local resection of the moid colon and fulguration of the lesions in rectum. Control observations were made in remaining 8 subjects (4 medical students, 4 ients admitted for repair of an inguinal nia). The colon of the normal subjects orbed Na and H_2O and secreted K. In patients h villous papilloma, Na and H_2O were secreted rates of K secretion were at least 10 times mean rate of normals. Na movement into the onic lumen was increased 5-fold, K 7-fold and 2-fold over the rate found in normals. es at which these substances moved from colon o body differed only slightly from controls. multiple polyposis, rates of net transport of K and H_2O lay within the range found in the mal group. Rates of unidirectional flux of were almost doubled; Na and K left the lumen the diseased colon 4-times more rapidly than mal and their rate of entry into the colonic en was also increased several-fold. In the ient with localized polyps, Na and H_2O were orbed at normal rates by the colon before and er resection of the polyp-bearing area of the moid colon and fulguration of the polyps in rectum. K was secreted 3-4 times more idly than in normals and this increased rate unaffected by polyp removal. Rates of directional movement of Na before and after ration did not differ significantly from mals. Unidirectional K movement into the onic lumen was increased, but rates of move- t in the opposite direction were normal. re was no appreciable alteration in rates of ransport after polyp removal.

3 PATHOLOGY OF AN EAST AFRICAN MEGACOLON.

(E.) Böhm, G. M. (U. São Paulo, zil) and B. Smith. Gut 7(6):662-665, 1966.

pathology of the intestine is described in 2 es of dilatation and hypertrophy of the gmoid colon from East Africa, occurring efly in the males of a single tribe. Material obtained from 2 male patients (one was 27 old, the other 55). In the first, the total gmoid colon was 65 cm long; the dilated part 27 cm long and 10 cm wide in its widest tion. The second sigmoid colon was 75 cm g and the dilated part 40 cm in length and 9 in its greatest diameter. In both cases latation occurred in the distal part of the gmoid colon and the rectum appeared normal. mucosa and submucosa were normal, but muscle coats were hypertrophied, especially the circular fibers. The quantity of unmyelinated nerve fiber in the intermuscular plexus was reduced compared both with the normal intestine and intestine distended behind a neoplastic obstruction. Schwann cell nuclei were large and more rounded than normal and considerably reduced in number. There was eosinophil infiltration of the plexus in places, but no other evidence of inflammatory reaction. Thick unmyelinated axons were present, but they were fragmented and occasionally swollen. The interlacing network of fine fibers was absent, except for a little axonal dust. This entity is a true megacolon, and degenerative changes in the sacral parasympathetic nerve supply may have been responsible for its development.

6224 ANO-TRANSABDOMINAL POLYPECTOMY: THREE-YEAR EXPERIENCE.

(E.) Benjamin, H. B. (Marquette U., Milwaukee, Wisc.), J. V. Herzog and B. Klamecki. Clin. Med. 74(1):39-41, 1967.

The ano-transabdominal method of polypectomy, whereby the polyp is removed from below, was used in a series of 85 patients without a single complication; in this series, 21 polyps were not palpated by the general surgeon, but were found by the proctologist. Morbidity was very low, with no more extension of hospital stay than is usual for elective major surgical intervention. This is an ideal method for use during elective surgery within the abdomen; polyps of the descending and sigmoid colon can be removed at the same time without a colotomy. The patient is much more comfortable after this technic, and feeding can be started as soon as desired. Other advantages of this method include direct visual inspection of the colon in difficult areas, direct visual inspection above the 25-cm level and discovery of polyps not detected by other diagnostic means, including X-ray technics.

6225 METACHRONOUS CARCINOMA OF THE LARGE INTESTINE AND INTESTINAL POLYPS.

(E.) Bussey, H. J. R. (St. Mark's Hosp., London), M. H. Wallace and B. C. Morson. Proc. Roy. Soc. Med. 60(3):208-210, 1967.

During a 30-yr. period (1928-1957), 3,381 patients survived operations for removal of malignant tumors of the colon or rectum; 65 were metachronous (the first cancer is followed by a second at a future date), but 12 were discarded from analysis for various reasons. The remaining 53 patients represented 1.57% of the total. The total series was divided into six 5-yr. groups; the 1928-32 group, which had been followed on the av. for 35 yr., contained slightly more than 3.5% of metachronous cancer cases. The incidence rates in the other groups fell in a fairly regular manner to 0.7% for those observed for 10 yr. The time interval between the initial and second primary cancers of the large intestine ranged from approx. 3 mo. to nearly 29 yr., with an av. of 8.5 yr.; 11 cases (20% of the total number) occurred in the first and second yr.; 31 of the 53 cases developed a second growth in the first 10 yr. after removal of the first cancer, 19 in the second 10 yr. and there were 3 more cases after 20 yr. The incidence rate showed a fairly regular rise with passage of time from 0.6% to nearly 2.0%, indicating that the longer patients survive the first operation for intestinal cancer the more likely they are to develop a second growth. None of the cases of metachronous cancer showed any association with ulcerative colitis. Approx. 50% of rectal cancers at their earliest stage arose in adenomas and villous papillomas. Data showed that a patient who had cancer associated with adenomas was twice as likely to develop a further intestinal cancer than when no polyps were initially present. There was a general tendency for the incidence rate to rise, but especially so in a group with adenomas observed for the longest time, where the incidence rate was approx. 4.5%. It is concluded that the presence of adenomatous polyps is associated with an increased liability to second carcinomas. A careful follow-up is advocated for all patients who have had operations for cancer of the large intestine.

6226 NEW TECHNICS IN THE SURGICAL TREATMENT OF HIRSCHSPRUNG'S DISEASE. (E.)

Ikeda, K. (Kyushu U. Sch. Med., Fukuoka, Japan). *Surgery* 61(4):503-508, 1967.

New technics for the treatment of congenital megacolon, consisting of a modification of Duhamel's procedure by means of an oval crushing clamp designed by the author, and a radical operation involving a Z-shaped anastomosis, are described; the latter is especially beneficial since it avoids the rectal pouch which is considered to be a major disadvantage of the Duhamel procedure. A total of 31 patients were treated, 12 with the oval crushing clamp (primary radical operation in 9, two-stage operation after colostomy in 3) and 19 with the Z-shaped anastomosis (primary radical operation in 8, 2-stage operation after colostomy in 8, recurrence after abdominal colectomy in 1 and stenosis after Duhamel-Grob operation in 2). There were 15 patients less than 1-yr.-old at operation, and 8 were less than 6 mo. old. The youngest was a 2-mo.-old child weighing 5.6 kg; this was an exceptional case since the radical operation is usually performed on those patients who are heavier than 6 kg and older than 3 mo. Of the 15 patients less than 1-yr.-old, 8 had a 1-stage procedure and 7 a 2-stage operation. Time required for the operation av. 112 min. (range, 100-135 min.); the operative time required for infants was less than that for older children. Only 5 patients were followed more than 2 yr. after the operation. There was 1 operation death (with the Z-shaped anastomosis). Early complications included mild wound infection in 1 and temporary stricture in 1 (both with the oval crushing clamp technic); late complications consisted of 1 case of mechanical ileus (in a case treated with the oval crushing clamp). Constipation and diarrh were not observed. There was no complaint of urinary incontinence since the anterior wall o the rectum remained intact.

6227 PRIMARY ADENOCARCINOMA OF THE APPENDIX. (E.)

Steinberg, M. (Louisiana State U. Sch. Med., New Orleans) an I. Cohn, Jr. *Surgery* 61(4):644-660, 1967.

An estimated 15,000 appendectomies were performed at Charity Hospital, New Orleans betwee 1942 and 1965 inclusive; the diagnosis of primary invasive adenocarcinoma of the appendix was made and appeared to be reasonable on case and slide review in only 2 patients (1 of whom had appendectomy elsewhere). In another case, coded as carcinoma *in situ*, the pathologists' opinions varied, the alternate diagnosis being villous adenoma. A fourth case is presented t illustrate certain diagnostic complications. The classification, incidence, pathophysiology treatment and prognosis of primary adenocarcin of the appendix are reviewed. A primary or secondary right hemicolectomy is recommended i all cases of this lesion, unless operative ris is prohibitive.

6228 ELECTROMYOGRAPHY IN THE MANAGEMENT C THE INCOMPETENT ANAL SPHINCTER. (E.

Haskell, B. (Jefferson Med. Coll. Hosp., Philadelphia, Pa.) and H. Rovner. *Dis. Colon Rectum* 10(2):81-84, 1967.

Patients (87) from 6-73 yr. of age with partia (perianal staining and seepage) to complete (fecal incontinence or rectal prolapse) anal incontinence underwent anal sphincter electromyography, performed by insertion of an appropriate electrode into representative quadrants of the sphincter muscle. Electrical activity at the myoneural junction was recorde on magnetic tape and photographic film and als yielded an audiovisual signal. The electrode was systematically repositioned at each site t insure wide sampling of muscle. Patients with normal electromyography (27 of 38) enjoyed successful sphincter rehabilitation and relief of symptoms as a result of galvanic stimulatio and coaching; the problem in most cases was helping the patients correctly identify contractions of the sphincter. Only 6 of 16 patients with abnormal electromyographic findings achieved satisfactory results with the training regime. Patients (5 of 7) with complete prolapse and less than 50% abnormal electromyographic samplings were successfully treated by amputative proctosigmoidectomy and postoperative sphincter rehabilitation. Patie (13 of 15) with more than 50% abnormal samplin

elderly poor-risk patients were successfully
ated by a modified Thiersch procedure per-
med by parasphincteric insertion of crimped
erial Teflon. Gracilis muscle transplant
the treatment of choice for complete
ontinence after electromyography of the
cilis muscles confirmed the degree of their
ervation. Success was obtained in 4 patients
s than 50 yr. of age; in 6 patients over
yr. arteriosclerotic changes prevented
ntenance of the transplant.

9 TECHNIC OF RETROGRADE COLONIC INTUBATION AND ITS INITIAL APPLICATION TO
H BIOPSY. (E.) Fox, J. A. (Roy. Free Hosp.,
don) and L. Kreel. Gut 8(1):77-82, 1967.

the 17 intubations, 5 were conducted using
ventional screening while the remaining 12
e carried out with the help of television
itoring. Biopsies were attempted in the
ter group, however only 11 cases proved
cessful. No episodes of hemorrhage or
udoperforation were seen in this series. The
unsuccessful biopsy resulted from inter-
ence of the biopsy apparatus by simultaneous
enema examination. In another case, the
on tube was improperly positioned resulting
biopsy of normal instead of pathological
sue. The colon tube is described in detail.
h colonic biopsy was reserved for in-patients
no sedative medication was employed unless
patient manifested anxiety. Following
sage of a sigmoidoscope to as high a level
possible, the colon tube is inserted into the
moidoscope. The sigmoidoscope is withdrawn
ving the tube in place. Care should be taken
prevent protrusion of the nylon stilette
ond the leading end of the colon tube, so as
preclude perforation. The colon tube is
sed to the desired level, the stilette and
iece are then withdrawn and the suction
psy tube inserted. Further biopsies can be
omplished at different levels by gradual with-
wal of the colon tube, thus providing a
posite picture of any colonic pathology.

0 COMPLICATIONS OF COLOSTOMY IN INFANTS AND YOUNG CHILDREN. (E.) Hartford,
E. (U. Iowa Coll. Med., Iowa City) and R. T.
er. J. Iowa Med. Soc. 57(13):229-232, 1967.

ostomies (23) were performed on 19 young
ients (15 boys, 4 girls), 9 of whom were less
n 1 yr. of age; the operation was done twice
4 cases. A total of 16 patients had colonic
nglionosis, while 3 had anomalies of the anus
l rectum. Loop transverse colostomy was done
12 patients. There were 5 deaths; all
urred within 4 days of operation. Of these,
ere moribund at celiotomy; 3 had severe
l/or multiple congenital anomalies and 1 with
nglionosis had perforation of the cecum and
itonitis. A fifth had Hirschsprung's
ease and died of peritonitis. Among 14
survivors, 12 of 19 had complications related to their colostomies; surgical treatment of the complication was required in 4 cases. Complications that required surgical treatment included colonic fistula, intussusception, intestinal obstruction and closure of the afferent loop. Those which did not require surgical treatment included hemorrhage (1), wound infection (2), intestinal prolapse (5) and pericolostomy skin irritation (7).

6231 CONTRIBUTION OF ENDOBIOPSY TO THE STUDY OF LATE ALTERATIONS OF THE RECTOCOLIC MUCOSA AFTER ROENTGEN THERAPY. (Rum.) Strat, C. (2nd Med. Clin., Iasi, Rumania), L. Wasserman, A. Boingeanu, E. Miron and V. Strat. Med. Intern. (Bucur.) 18(9):1039-1047, 1966.

In 24 patients with colorectitis ascribed to irradiation 2 mo.-2 yr. earlier for cancer of the uterine cervix, endobiopsy revealed regressive lesions of the mucosa of the covering epithelium and crypts, marked by disappearance of the mucosecretory cells and the appearance of conspicuous metaplasia. These findings were accompanied by dystrophic lesions of the smooth muscle fibers and of the muscularis mucosae, arteriosclerosis, venous insufficiency, and lymphostasis with hyalinization of the lumina and thrombosis of the lymph vessels. As these lesions progress, interstitial sclerosis develops. The gravity of these lesions, some of which must be regarded as precancerous changes, calls for periodic clinical and morphologic checkups of rectal disorders in irradiated patients.

OBSERVATIONS ON THE ABSORPTION OF ORAL
BETAMETHASONE 17-VALERATE AND ITS
APEUTIC VALUE IN ULCERATIVE COLITIS. (E.)
dman, M. (Univ. Coll. Hosp., London), J.
cher, J. M. Hinton, J. E. Lennard-Jones,
. Misiewicz and J. A. Parrish. Brit. Med.
(5536):335-337, 1967.

methasone 17-valerate was thought to be an
ctive treatment for ulcerative colitis
h causes neither adrenal suppression nor
r steroid side-effects. However, adrenal
ression (plasma cortisol levels less than
/100 ml) occurred in all of 6 normal sub-
s who were admin. 8 or 12 mg/day of the
p.o., thus showing that absorption did not
r. In a clinical study of 27 patients with
cute attack of ulcerative colitis, 17 were
n either 4 mg or 8 mg of the drug/day; only
17 showed improvement. Of 10 patients in
adrenal suppression was studied and who
given 8 mg/day, 3 improved, but none of
e were in complete remission at 4 wk.;
nal suppression occurred in 3 of 10 patients.
7 who did not improve on betamethasone 17-
erate all subsequently improved on
lnisone (30 mg/day, p.o.) or on sulfasalazine
.) and prednisolone-21-phosphate retention
nas. It is concluded that betamethasone 17-
rate (p.o.) is not a satisfactory treatment
ulcerative colitis in the dose used in this
dy.

3 MODERATE RECTAL FREEZING IN THE TREAT-
MENT OF HEMORRHAGIC RECTOCOLITIS.
LTS IN 13 PATIENTS. (Fr.) Debray, C.
chat Hosp., Paris) and F. Besançon. Sem.
. 43(1):17-19, 1967.

tal freezing was performed on 19 occasions in
patients with recurrent rectocolitis (4
ients underwent 2 procedures and 1 was
ated 3 times), without interruption of cur-
t medical therapy (not described). One
ient was not evaluable at the time of report;
ailed to respond and 2 later developed
urrences (1 immediately, the other after a
d response). The other 15 courses induced
ked and very rapid improvement. Particularly
d responses were noted in 5 patients (under-
ng 7 procedures); 3 of these patients had
n scheduled for surgery, but showed such
ked improvement after rectal freezing that
orectal anastomosis was no longer required.
patient treated 3 times showed marked im-
vement after each procedure. Gastroscopic
dings were also markedly improved. The
ation of remissions was no longer than that
spontaneous remissions; 3 patients remained
remission after about 5 mo. and the others
apsed after 1-9 mo. (av. 5 mo.).

4 EXPERIMENTAL PRODUCTION OF HEMORRHAGIC
ULCERATIVE COLITIS WITH AUTOANTIBODIES.
(Fr.) Oriol Palou, R. (Broussais Hosp., Paris), B. Halpern, A. Zweibaum, J. C. Morard, C. Veyre and A. Abadie. Med. Hyg. (Geneve) 25(763): 62-64, 1967.

In Wistar rats, intraplantar admin. of antigen from canine colon mucosa (corresponding to 25 mg fresh tissue in an equal vol. of Freund's adjuvant; 2 inj. at a 10-day interval) led to the development of hemorrhagic ulcerative colitis. Specific autoantibodies (anti-A) developed in the serum, reaching max. levels after 17 days and decreasing to nearly zero after about 4 mo. The syndrome, confined to the colon, included hemorrhagic ulcerations of the colon mucosa and chronic clinical signs (diarrhea and hemorrhage) which fluctuated in severity over several mo.; it was nearly identical to the ulcerative colitis syndrome in man. Treatment with homologous colon tissue or Freund's adjuvant alone did not induce this syndrome.

6285 LIVER IN ULCERATIVE COLITIS: OBSTRUCTIVE JAUNDICE DUE TO BILE DUCT CARCINOMA. (E.) Rankin, J. G. (U. Melbourne, Australia), A. P. Skyring and S. J. M. Goulston. Gut 7(5):433-437, 1966.

In a series of 441 patients with ulcerative colitis, 3 patients (2 women, 1 man) had bile duct carcinoma. In the same series, pericholangitis, which occurred in 26 patients, was the most common significant hepatic lesion. The frequency of the association of ulcerative colitis and bile duct cancer in this and other series suggests a specific relationship, the basis of which is still undetermined. Two of the patients died from cancer of the bile ducts at the unusually early age of 22 yr. The 3 patients had suffered from colitis for 10-14 yr. before clinical evidence of bile duct cancer occurred; in 2 cases clinical evidence of tumor appeared 9 and 18 mo., resp., after colectomy. In 2 patients the lesion was situated at the lower end of the common hepatic duct, while the third patient had an intrahepatic cholangiocarcinoma arising from the right hepatic duct. The association of the 2 diseases may be genetically determined, or bile duct carcinoma may be a complication of ulcerative colitis and may possibly be related to the inflammatory changes found in the biliary epithelium of many patients with the latter disease.

6286 EARLY ULCERATIVE COLITIS IN CHILDREN AND ADOLESCENTS. (E.) Brahme, F. (Indiana U. Med. Ctr., Indianapolis). Dis. Colon Rectum 10(2):136-140, 1967.

Roentgenologic changes in the early stages of ulcerative colitis in 45 patients less than 20 yr. of age (32 were less than 15 yr. old; 10

were 10 yr. old or younger) are described; 5 patients were examined within 14 days after onset of symptoms, and 32 were examined within 3 mo. In almost all patients less than 15 yr. old, lesions were equally severe in all the involved segments of the colon; in patients 15-20 yr. old, lesions were generally much more marked in the rectum and left half of the colon and faded as they extended cephalad. In 29 of 32 patients mucosal lesions initially affected the entire colon; in only 3 patients were lesions confined to the rectum. In patients from 16-20 yr. old, lesions were confined to the rectum in 4 patients, and in 6 they were limited to the rectum and sigmoid flexure. In only 3 of 13 patients of this group were the entire colon and rectum involved. In 12 of 32 patients less than 15 yr. old, ulcers healed, leaving a completely normal colon except for the obliterated folds of Kohlrausch. Strictures developed in 4, but deep undermining ulcers were not seen in this group. No cancer was encountered in this series. In patients older than 15 yr., changes were mainly confined to the left half of the colon; in 2, deep ulcers and pseudopolyposis developed. Three had changes in the rectum and entire colon, similar to those seen in the younger group, and in 2 the lesions healed completely. All patients in this group also had lesions in the rectum. In 29 of 32 cases, a juvenile type of distribution of lesions was found; the adult type of distribution (localized mainly in the rectum and sigmoid flexure) began at approx. 15 yr. of age. Healing of extensive lesions was observed, and prognosis was not related to th initial extent of the disease.

6291 TOTAL COLECTOMY WITH IMMEDIATE ILEORECTOANASTOMOSIS IN THE SURGICA TREATMENT OF ULCERATIVE COLITIS. (It.) Nico E. (Galliera Hosp., Genoa, Italy) and G. Vent *Rass. Arch. Chir.* (*Genova*) 4(6):285-318, 1966

A TEN-YEAR EXPERIENCE WITH CARCINOMA
OF THE PANCREAS. A COOPERATIVE STUDY.
Foster, J. H. (Hartford Hosp., Conn.).
. Surg. (Chicago) 94(3):322-325, 1967.

a 10-yr. period (January 1, 1955-December
1964) a total of 564 patients with proven
inoma of the pancreas were treated in 7
ral hospitals in Portland, Oregon. A total
60 patients (82%) had histologic confirma-
of the diagnosis of pancreatic carcinoma at
rotomy or at autopsy. Excluding those at
Veterans Admin. Hospital, 62% of the
ents were male. In total, 27 (5%) under-
resection, with an av. survival of 18.1 mo.
operative mortality of 22%; 248 underwent
ss, with an av. of 5.4 mo. survival and an
ative mortality of 18%, while 194 underwent
rotomy, without bypass or resection, with a
. av. survival time and a 25% operative
ality. Only 2 patients survived resection
than 5 yr. without evidence of tumor, but
other 19 patients who underwent resection
d an av. of 15 mo. which was 3 times the
ival time of patients who had undergone
ssing operations without resection. It is
luded that resection should be done
equently for pancreatic carcinoma and then
when the most favorable circumstances
t; nevertheless, significant palliation can
chieved in this group and the disease will
ermanently eradicated in an occasional
ent.

3 CARCINOMA OF THE PANCREAS. A
STATISTICAL, CLINICAL AND PATHOLOGICAL
Y. (E.) Klintrup, H.-E. (Univ. Cent. Hosp.,
inki, Finland). Acta Chir. Scand.
Suppl. 362):1-96, 1966.

incidence, clinical characteristics, surgical
tment, structure and mode of growth of
reatic carcinoma are discussed; material
uded 1,556 cases of pancreatic carcinoma
rted to the Finnish Cancer Register during
-60; 191 cases treated during 1952-63 at the
ersity Central Hospital, Helsinki (117 men,
omen; av. age was 53.5 yr.; surgery,
ormed on 179, included 23 radical, 109
iative and 47 exploratory; in 72% of the
s the diagnosis was verified histologically);
94 cases found in 5,666 autopsies during
-63. Annual incidence in 1954-60 av. 5.2
cases/100,000. An av. of 250 new cases
diagnosed annually, 20-25 of which were
inomas of the papilla of Vater. The disease
twice as frequent among men, but in older
groups the percentage increased among women.
number of cases diagnosed, and their degree
erification, was greater in cities than in
countryside. Radical surgery, performed on
was not curative. After palliative surgery,
ormed in 33% of the cases, mortality rate
ng the first yr. was distinctly, and in the second yr. slightly, lower than among untreated patients. Five-yr. survivals among the 1,556 Cancer Register cases numbered 34; 2 had been treated with radical and 17 with palliative surgery, while 15 had no treatment. Histological verification existed in 9 cases. Wt. loss was seen in 73% of the cases; pain was associated with 25% of tumors of the papilla of Vater, 59% of those of the head of the pancreas, and 84% of those of the body and tail of the pancreas. Jaundice was present in 100% of the tumors of the papilla of Vater, 84% of those of the head and 18% of those of the body. Painless jaundice occurred in 34% of all cases, and a positive Courvoisier sign in 16%. Duration of symptoms before surgery av. 5 mo., and for those treated with radical surgery, 2.8 mo. Diabetic metabolism occurred in 10% of the clinical series, and in 12% of autopsies. Venous thrombosis was infrequent in the clinical series and occurred in 19% of the autopsy material. Cholelithiasis occurred in 20% of the cases. Diagnosis was made chiefly during surgery by palpation. Eleven percent of the cases were eligible for radical surgery; mortality of radical operations in 23 patients was 9%; postoperative morbidity was 30%. Mortality was 17% for palliative operation. Pancreatico-duodenal resection was the primary form of treatment for cancer in the pancreatico-duodenal region; cancer of the papilla of Vater was the main criterion. Altogether, 75% of the tumors were located in the head of the pancreas; by histological type, 62% were ductal, 16% acinar and 22% intermediate. Characteristic growth was by local infiltration, especially into retropancreatic tissue. Inoperability was due to infiltration in 90% of the cases in which symptoms had a duration of 3 mo. or less. Metastases were found, especially in the peritoneum, liver and regional lymph nodes. No macroscopic metastases were seen in 23% of the autopsies. Perineural infiltration typical of pancreatic carcinoma was noted in 61% of the cases. No conclusive correlation was demonstrable between histological type and degree of malignancy, on the one hand, and local infiltration, metastases and perineural infiltration, on the other. Carcinomas of the papilla of Vater showed a slower growth and a lower incidence of infiltration and metastases; they contained the highest percentage of operable cases and the av. survival period was longer than in carcinoma of the pancreas, even after palliative surgery.

6294 EVALUATION OF PALLIATIVE OPERATIONS
FOR CARCINOMA OF THE PANCREAS. (E.)
Bufkin, W. J., P. E. Smith (U. Miami Sch. Med.,
Fla.) and E. T. Krementz. Arch. Surg. (Chicago)
94(2):240-242, 1967.

Of 26,087 patients treated for neoplastic diseases at the New Orleans Charity Hospital from January 1, 1948 to December 31, 1963, 600 (2.3%) were treated for cancer of the head of the pancreas; 157 of these had disease requiring a palliative operation for bypass of the obstructed common bile duct. In 149 (95%), the gallbladder was anastomosed to either the stomach, duodenum or jejunum; in 8 (5%) the common bile duct was used. Of 157 patients, 25 (16%) died in the hospital. Av. survival time for patients treated with some type of bypass operation was 4.7 mo., while av. survival time of patients with cancer of the head of the pancreas, in this series, was 3.2 mo.; patients discharged from the hospital lived an av. of 5.3 mo. A total of 80 patients (54%) had biochemical evidence of a fall in serum bilirubin; the av. fall was 11.0 mg/100 ml. Loop cholecystojejunostomy was used most frequently (78%); 25% of the patients who had loop jejunostomy bypass operations had a concomitant jejunojejunostomy distal to the primary anastomosis. Prophylactic or therapeutic gastrojejunostomy was done on 15 patients to offset concomitant or imminent duodenal obstruction. Of the patients who received a bypass operation using the gallbladder, 85% were discharged; only 63% of those receiving a bypass operation using the common bile duct were discharged. Of those receiving bypass operations using the gallbladder, 83% showed clinical improvement, but only 50% of those receiving bypass using the common bile duct showed improvement. Twenty-one patients (62%) who had a Roux-en-Y operation improved, but there was a greater decrease in serum bilirubin after this operation. Some complications during or after operation occurred in 31 patients (20%) who received bypass operation; these included psychosis, azotemia, shock, wound infection, pneumonia, alkalosis, acute renal failure and gastrointestinal hemorrhage. Most patients lived less than 3 mo., but 2 survived 23 mo. and 36 mo., resp. It is concluded that simple loop cholecystojejunostomy has the lowest operative fatality and produces the greatest percentage of clinically improved patients.

6295 PSEUDOCYST OF THE PANCREAS. REPORT OF FIVE CASES AND REVIEW OF LITERATURE.

(E.) Wool, G. (St. Louis Children's Hosp., Mo.) and D. Goldring. J. Pediat. 70(4):586-594, 1967.

Five patients (4 female, 1 male; 19 mo.-6 yr. old) with pseudocyst of the pancreas were treated at the St. Louis Children's Hospital during the last 45 yr.; a review of the literature disclosed that only 47 other cases had been reported during the last 57 yr. A review of the literature which is presented includes a discussion of the age, sex, histology, etiology, pathogenesis, laboratory findings, signs and symptoms, differential diagnosis and treatment of pancreatic pseudocyst. There was a history of preceding trauma in 54% of the 52 cases, and a history of antecedent infection in 25% of the cases. Significant anemia occurred in 2 of the 5 children reported herein, and serum amylase
levels were elevated in 3 of 5. Treatment of
pseudocyst is surgical, including cystogastro
tomy, cystojejunostomy and cystoduodenostomy;
internal drainage is associated with the best
results. In the 5 cases reported, the 3 earl
ones had excision or external drainage of the
pseudocyst, while the 2 recent cases had cyst
gastrostomies. With proper treatment, progno
is considered to be excellent.

6296 STUDIES ON THE CONTENT OF ELASTASE
THE PANCREATIC SECRETION TEST. (Ge

Schoenemann, J. (U. Rostock, Germany). Deuts
Z. Verdau. Stoffwechselkr. 26(3):129-133, 196

The conc. of pancreatic enzymes, amylase,
trypsin elastase and proelastase were determined in the duodenal fluid of 11 fasting
patients; a duodenal intubation with double
balloons was used to obtain the duodenal jui
fraction A, after s.c. inj. of 15 mg mecholy
after aspiration of a 10 min. fraction 75 U
secretin were inj. i.v. Further fractions w
obtained 20, 40, 60, and 80 min. after admin
of methacholine (mecholyl). Proelastase and
elastase conc. were measured by a photometri
method as U/ml of duodenal juice. Proelasta
of the gland and in fresh pancreatic juice i
rapidly converted to elastase by trypsin.
Amylase and trypsin were determined by
conventional methods. In the normal subject
the conc. of elastin, trypsin and amylase we
parallel in the fractions taken up to 40 min
and still quite close in the following fract
In pernicious anemia the conc. of trypsin an
elastase varied in the same manner whereas t
amylase conc. was markedly increased; this
situation also was obtained in chronic pancr
although the amylase conc. was only moderate
elevated. The conc. of bicarbonate was also
measured in the samples of duodenal juice;
bicarbonate was elevated to the greatest deg
in pernicious anemia after the inj. of secre
reaching a conc. of twice the normal.

6297 EXPERIMENTAL REFLUX PANCREATOGRAPH
AND CHOLANGIOGRAPHY. (E.) Waldro

R. L. II (Columbia-Presbyterian Med. Ctr.,
New York City), D. G. Bragg, W. J. Daly and
W. B. Seaman. Radiology 88(2):357-360, 1967

Intraluminal balloons were placed operativel
into each of 7 different adult mongrel dogs
both sexes. In this way, the duodenal segme
containing the openings of the biliary and
pancreatic ducts was isolated. The isolated
loop was filled with 50% Hypaque in an effor
to attain reflux through the openings of the
biliary and pancreatic duct systems. Using
pressure alone, no reflux occurred. Reflux
occur after 250-500 mg aminophylline was inj
i.v. and 1% Xylocaine was instilled into the
isolated loop for a period of 15-20 min. an
then withdrawn. In 5 dogs, reflux occurred
through the biliary duct opening and in 2 d
of the 5 it occurred through the pancreatic
duct. In 2 dogs, no reflux occurred because

iliary duct opening was found to be tly occluded by the proximal balloon. er Xylocaine nor the aminophylline alone ced any reflux. It is suggested that this ic will be of significant value in attain- irect pancreatography and may possibly be er approach to cholangiography.

See also abstract nos.: 5630,5636,5722,5726,5727,5729,5730,5731,5732,5761,5849,6566

6305 ACUTE PANCREATIC NECROSIS INDUCED BY PUROMYCIN. (E.) Longnecker, D. S. (U. Pittsburgh Sch. Med., Pa.) and E. Farber. Lab. Invest. 16(3):321-329, 1967.

Rats developed patchy necrosis of pancreatic acinar cells after treatment with puromycin for periods of from 4-8 hr. Generally the degree of acinar cell necrosis was proportional to the dosage level of puromycin in the range of 5-40 mg/kg/hr. A definite, but incomplete, inhibition of incorporation of ^{14}C-leucine into pancreatic protein occurred in rats treated with puromycin at 20 mg/kg/hr. At higher doses of puromycin, lesions were also observed in the submaxillary salivary gland, lymphoid tissue and the gastrointestinal tract. Two hypotheses, one implicating inhibition of pancreatic protein synthesis and the other the production of peptides secondary to inhibition of protein synthesis, are proposed as possible pathogenetic mechanisms.

6306 LONGITUDINAL PANCREATICOJEJUNOSTOMY IN ALCOHOLIC PANCREATITIS. (E.) Cox, W. D. and W. J. Gillesby (145 Virginia St., Crystal Lake, Ill.). Arch. Surg. (Chicago) 94(4):469-475, 1967.

A total of 86 patients (24-55 yr. old, mean age 36 yr.; most of whom were male) with proven alcoholic pancreatitis were studied; 34 had no history of a previous attack, 10 had 1 attack and 42 had 3 or more previous attacks. Complications due to pancreatitis included shock (10), obstructive jaundice (12), diabetes mellitus (11), delirium tremens (14), steatorrhea (12), pancreatic calcification (8), pseudocyst (7), hyperlipemia (5), pneumonia (4), abscess of the lesser sac, uremia and extra-abdominal fat necrosis (2 each) and Mallory-Weiss syndrome (1). There were 13 deaths (14.3%). A total of 32 patients underwent pancreaticojejunostomy; 5 of these had previous cystogastrostomies that had closed. Complications of pancreaticojejunostomy included wound infection and fistula (3 each), and 1 each for hemorrhage, anesthetic overdose, peritonitis and subphrenic abscess. Follow-up ranged from 8-48 mo. Obstructive jaundice was relieved in 3 of 4 patients; return of pancreatic exocrine function was documented in some cases in about 6 mo., by disappearance of steatorrhea and floating stools, and by gain in wt. Four patients were rehospitalized: 2 due to acute alcoholic brain syndrome with delirium tremens, 1 with cirrhosis of the liver and one (4 times) for alcoholic gastritis and acute intoxication with no evidence of serum amylase elevation. None have abstained from imbibing alcohol. None of the 32 patients operated upon have been readmitted for a recurrent attack of pancreatitis.

6307 TRASYLOL IN ACUTE PANCREATITIS. (E.) Trapnell, J. E. (Roy. Infirm., Bristol, England), C. H. Talbot and W. M. Capper. Ame J. Dig. Dis. 12(4):409-412, 1967.

A double-blind trial was conducted in which 2 patients with acute pancreatitis received Trasylol (2,000-20,000 U) by either i.v. inj. or i.v. infusion, while a control group of 24 subjects received an equivalent vol. of sali dextran by the same routes; in both groups th av. age of the patients was 61.5 yr. Trasylo conferred no benefit; there was no significan difference in morbidity or mortality between the 2 groups. In the Trasylol-treated group there were 4 deaths. The av. duration of pa was 3.7 days and the av. duration of paralyt ileus was 5.3 days; in controls, these parameters were 2 deaths, 3.4 days and 4.0 days, resp. There is some evidence, both clinical and experimental, to suggest that a further double-blind trial of Trasylol using very mu larger doses would be valuable. It is recommended that if Trasylol is given for ac pancreatitis, at least 200,000 U/day should admin. and that a close observation be made toxic effects.

6308 THE MANAGEMENT OF SEVERE ACUTE PANCREATITIS. (E.) Louw, J. H. (Cape Town, South Africa), I. N. Marks and S. Bank. Postgrad. Med. J. 43(495):31-44, 1967

Classification of severe acute pancreatitis (42% of 584 total cases of pancreatitis) included alcoholic, biliary, miscellaneous a idiopathic with single and recurrent attacks comprising 80 and 168 cases, resp. The numb of complications (shock, 50; pleural effusio 5; gastrointestinal hemorrhage, 21; acute diabetes, 33; acute steatorrhea, 5; metastat fat necrosis, 7; abscess, 7; cyst formation, 48; duodenal obstruction, 2; and common duct obstruction, 2) based on type of pancreatiti included alcoholic (107), biliary (30), miscellaneous (24) and idiopathic (19). The mortality rate was 8.4% overall with 4.7%, 15.5%, 8.3% and 20% for alcoholic, biliary, miscellaneous and idiopathic categories, res Primary deaths (9) were attributable to simp shock (2), to shock with hemorrhage (1), wit hemorrhage and acute diabetes (1), with acut diabetes (2), with metastatic fat necrosis (with hyperlipemia (1) and to simple dissemin lupus erythematosis (1). Postoperative deat (12) were associated with laparotomy (shock, shock and hyperlipemia, 1); abscess drainage (shock, hemorrhage and sepsis, 1); abscess drainage and cholecystectomy (shock and seps 1; shock, hemorrhage and sepsis, 1); externa drainage of cyst (hemorrhage, 1; fistula an sepsis, 1); choledochotomy (hemorrhage, 3); sphincterotomy (hemorrhage, 1) and gastroenterostomy (hemorrhage, 1). Treatment consisted of conservative therapy (117); ea laparotomy (50); early laparotomy with dela

initive surgery (1); early laparotomy with
initive surgery (15); and delayed definitive
gery (5) which corresponded to 9,2,0,3,1 early
ths, resp. and 15(9%), 2(4%),0,3(20%),0, and
total deaths, resp. In the conservative
up there were 32 separate subsequent operations
complications and 6 late deaths.

9 SURGICAL INDICATIONS AND LATE RESULTS IN 90 CASES OF DIFFUSE CHRONIC AUTON-
JS PANCREATITIS. (Fr.) Salembier, Y. and
Ribet. Lyon Chir. 62(6):835-840, 1966.

90 patients undergoing surgery, 60 were
ilable for long-term follow-up (12-18 mo. in
over 2 yr. in 54); 123 surgical procedures
e performed and 28 patients underwent a
gle procedure. In general, surgery was as
servative as possible. Prolonged external
inage gave good results, especially when
tisone (25-100 mg/day) was added to the
imen; biliodigestive anastomosis was also
ective. Splanchnicectomy resulted in good
frequently only temporary responses. Caudal
createctomy (usually together with another
cedure) was performed in 9 patients, with
d results in 4 and a moderately good response
l. The response rate was much better in
ients who abstained from alcohol after treat-
t (70%) than in those who did not (35%).

0 ACUTE PANCREATITIS AFTER GASTRECTOMY.
(Fr.) Karageorgis, B. (Piree Gen.
p., Athens, Greece) and S. Milingos. Lyon
r. 62(6):862-868, 1966.

te pancreatitis developed 5-10 days after
lroth II gastrectomy in 7 of 1425 patients
42%) with duodenal (6) or gastric (1) ulcers.
4 patients the symptoms of pancreatitis were
omplicated and conservative therapy
piration, plasma, electrolyte replacement,
haneheline Banthine), antienzymes; hydro-
tisone in 1 patient) resulted in significant
rovement without the necessity for subsequent
gery. The other 3 patients showed other
ptoms (subicterus in 2) and underwent drain-
after conservative therapy failed to reverse
process completely. Two patients responded
l, but 1 patient (with a perforated ulcer
ending to the pancreas) showed pancreatic
rosis and widespread abdominal steatonecrosis
laparotomy and died 3 days later. Traumatiza-
n of the pancreas (6) or Santorini's duct (1)
responsible for the development of pan-
atitis. Technical methods to prevent this
ury are discussed.

1 HISTOCHEMICAL TOPOGRAPHY OF ACTIVE PROTEASES IN EXPERIMENTAL AUTODIGESTIVE
CREATITIS. (Ger.) Bleyl, U. (U. Heidelberg,
many), K. H. Grözinger, W. Nagel and M. Wanke.
chow. Arch. Path. Anat. 342(1):26-37, 1967.

Ten mongrel dogs had an experimental pancreatitis induced under anesthesia by the intracanalicular introduction of 6 ml of olive oil; 2-5 hr. after the application of olive oil, the animals were killed and the pancreata removed; some tissue from each gland was prepared for optical histology; some tissue was frozen and sectioned for histochemical studies using a modified fibrin substrate-film method by applying beef fibrinogen to sections treated with a thrombin preparation. These moist sections were incubated at 37°C for 10-60 min., fixed in 5% formalin, stained, and covered as usual. The moist sections were incubated without, and also with, the addition of Ca ion. The fibrin film was digested away in broad, rounded or oval areas in the regions of the intrapancreatic blood vessels, after short incubation periods (about 10 min.) without the Ca ion. When the Ca ion was present, no fibrinolysis occurred. Parallel effects were seen on longer incubation (more than 30 min.) in the pancreatic tissue and in the overlying fibrin film. This *in vitro* proteolysis seems to be the same as that occurring in autodigestive pancreatitis. The proteolytic digestion of the substrate in the parenchymal regions differed, however, from the perivascular (endothelial cell) plasmin-induced fibrinolysis by its relationship to areas of tryptic necrosis. Regions of extensive necrosis showed absence of the substrate film. The Ca ion slowed the plasminogen-activated fibrinolysis. Proteolysis was not delayed by the Ca ion in the regions of autodigestive parenchymal (tryptic) necrosis. Proteases released from tissues are important in the pathogenesis of autodigestive pancreatitis.

6312 STUDIES ON THE CARBOHYDRATE METABOLISM IN TOXIC PANCREATITIS OF RABBITS.
(Ger.) Bibergeil, H. (U. Med. Clin., Rostock, Germany). Z. Gastroent. 4(6):352-358, 1966.

The pancreatitis resulting from inj. of 3-5 ml of a standardized, diluted staphylococcus toxin under a pressure of 45-70 cm H_2O into the pancreatic duct of each of 10 rabbits (Group 3) (3.9 kg) followed by duct ligation, caused a hyperglycemia from short term (in the first 60 min. after inj.) to one lasting for several hours; after 24 hr. the blood sugar level had returned nearly to normal; postoperatively, 3 days and 5 wk. after the operation Group 3 was given prednisolone-glucose tolerance tests (1 g glucose/kg in 40% soln., 2 hr. after 2.5 mg prednisolone, i.v.); these tests were compared to those given prior to toxin inj. Eight different animals with a sham operation and pancreatic duct ligation (Group 2) and 10 animals with sham operation only (Group 1) served as controls. Group 2 had elevated blood sugar levels although not as high as Group 3. The av. serum amylase activity of Group 2 reached 3773 μg of converted starch at the end of 24 hr., exceeding Group 3 by 1118 μg. The amylase values had receded to the normal range 4 wk. after operation. The prednisolone-glucose tolerance tests given postoperatively showed an increased and prolonged blood sugar level in Groups 2 and 3 to almost the same extent, decreasing somewhat more slowly in Group 3; 3 days as well as 5 wk. after operation, all showed a normal tolerance test. After 5 wk. all animals except Group 1 developed a definite diabetes, of a lower grade in Group 2 than Group 3. The experimental results corresponded to the rapid, transitory hyperglycemia in acute pancreatitis of man and that type of permanent diabetes observed in the clinic after total necrosis of the pancreas. This was confirmed by histology.

ACIDIFICATION OF THE DUODENUM AND
ELIMINATION OF SULFOBROMOPHTHALEIN
THE CIRCULATION. (Ger.) Benyó, I. (U.
pest, Hungary), F. Füsy, P. Görgö and M.
z. Deutsch. Z. Verdau. Stoffwechselkr.
):134-137, 1966.

ents with normal gastrointestinal function
the residual gastric juice aspirated from
fasting stomach after which 2 ml/kg of
iological saline at body temperature was
illed into the duodenum. BSP dye (5 mg/kg)
inj. in 1 cubital vein; at 3,7, and 15 min.
r dye inj., blood samples were taken from
contralateral vein and the dye conc.
rmined in the serum. The same procedure
repeated 48 hr. later, exactly, except that
% HCl (2 ml/kg) was substituted for the
iological saline. Significant differences
limination of dye was found between the 2
of tests carried out in 10 patients. The
erence was appreciable at 3 min. after dye
but became more marked at 7 and 15 min.; at
n. 26% more dye was eliminated after
ification of the duodenum and at 15 min.
ination was 59% greater after acidification.
e is no certain explanation for this effect;
transfer of the dye in the reticulo-
thelial system may be hastened. However, it
mportant that the BSP test be given in the
ing on a fasting stomach in order to
dardize the test as far as possible.

HISTOCHEMICAL STUDY OF ENZYMES IN THE
LIVER IN CHRONIC HEPATITIS AND
RHOSES OF THE LIVER. (Rus.) Gupalo, E. E.
. Pathol. Anat., Inst. Therapy, Moscow).
. Pat. 28(11):62-66, 1966.

activity of succinic dehydrogenase, cyto-
ome oxidase, nonspecific esterase, and true
ase in liver samples, collected by laparoscopy
n 19 patients suffering from cirrhosis and 9
ients with chronic hepatitis, was determined
histochemical methods and compared with the
ivity of these enzymes in liver of healthy
ividuals. The levels of succinic dehydro-
ase, cytochrome oxidase, and nonspecific
erase were markedly lower in affected than
normal livers. However, in regenerating
er cells the activity of succinic dehydro-
ase and of nonspecific esterase increased
in rapidly. On the other hand, the level of
e lipase was higher in affected than in nor-
livers. The localization of these enzymes
various cell types of affected and normal
ers is also described.

5 ELECTROPHORETIC MOBILITIES OF SERUM
γ-GLUTAMYL TRANSPEPTIDASE AND ITS
NICAL APPLICATION IN HEPATOBILIARY DISEASE.
) Rutenburg, A. M. (Beth Israel Hosp.,
Boston, Mass.), E. E. Smith and J. W. Fischbein. J. Lab. Clin. Med. 69(3):504-517, 1967.

The electrophoretic mobilities of the isoenzymic components of γ-glutamyl transpeptidase in normal serum and in the serum of 52 patients with various hepatobiliary and other diseases is described. Paper electrophoresis of normal serum separates γ-glutamyl transpeptidase into 2 fractions, one in the albumin to α_1-globulin region (GT-1) and a major one in the α_2-globulin region (GT-2). In electrophoregrams of patients with disorders affecting hepatobiliary and pancreatic systems, there was a relatively large increase in GT-1, compared to GT-2, and frequently there was an abnormal peak in the β-globulin region (GT-3). A dominant GT-3 peak was noted in patients with biliary cirrhosis secondary to choledocholithiasis or biliary atresia and in some patients with liver metastases and severe toxic hepatitis. Prognosis was usually poor when the GT-3 fraction was dominant. In patients with hepatobiliary pancreatic disease, the principal value of glutamyl transpeptidase electrophoresis is in evaluating prognosis and progress of disease and response to therapy rather than in differential diagnosis.

6326 INDOCYANINE GREEN CLEARANCE AS A TEST FOR HEPATIC FUNCTION. EVALUATION BY DICHROMATIC EAR DENSITOMETRY. (E.) Leevy, C. M. (VA Hosp., East Orange, N. J.), F. Smith, J. Longueville, G. Paumgartner and M. M. Howard. J.A.M.A. 200(3):236-240, 1967.

Clinical evaluation of liver function was facilitated by use of dichromatic ear densitometry to study the clearance of indocyanine green; densitometry provides an accurate index to arterial levels of this dye. Hepatic clearance studies were obtained in 10 healthy adult subjects (25-60 yr. old) who had histologic evidence of a normal liver and 49 patients in the same age group with biopsy evidence of liver disease (10 fatty liver, 11 viral hepatitis, 18 Laennec's cirrhosis, 3 postnecrotic cirrhosis, 4 cancer metastases to the liver and 3 extrahepatic biliary obstruction); 0.5 mg and 5.0 mg of indocyanine green/kg body wt. were used. Sequential clearance studies in the same patient with increasing doses of the dye showed that patients with mild liver injury could be differentiated from those with normal liver. Subjects with normal removal of both 0.5 and 5.0 mg of the dye had normal results of liver histology or hepatic infiltrative lesions such as fat or metastatic cancer not associated with other morphological evidence of liver-cell damage. Those with normal removal of 0.5 mg/kg and abnormal removal of 5 mg/kg had evidence of liver-cell damage or necrosis on biopsy; this was associated with fatty liver, mild cirrhosis, metastatic cancer, early-phase cholestasis or viral hepatitis. Patients with abnormal removal at both low and high dose levels consisted of patients with marked fatty liver, acute hepatitis, moderate to severe cirrhosis and late phases of biliary obstruction or cancer metastases to the liver. Removal of the large dose was abnormal in patients with histologic evidence of mild fatty liver (4 patients) or persistent mild hepatitis (3 patients) in whom serum total bilirubin level, SGPT and 45-min. BSP retention were normal. Clearance capacity for 5 mg indocyanine green/kg body wt. returned to normal later than either SGPT or BSP retention in 3 patients with active viral hepatitis studied serially. Long-term studies in patients with Laennec's cirrhosis or postnecrotic cirrhosis showed an increase in dye clearance with improvement in histopathology and deterioration in dye-removal capacity with morphological evidence of further liver-cell destruction. It is concluded that serial study of indocyanine clearance reflects improvement or deterioration in liver histopathology and is valuable in following the course of both acute and chronic liver injury.

6327 CONTINUOUS INDOCYANINE GREEN DISAPPEARANCE CURVES AS A ROUTINE LIVER FUNCTION TEST. (Fr.) Platteborse, R. (Saint Gilles Hosp., Brussels, Belgium), M. Clausse and C. Tenzer. Acta Gastroent. Belg. 29(10):831-846, 1966.

In 26 normal adults, the av. blood clearance of indocyanine green was 6 min. 2 sec., and av. values for arm-ear and ear-ear circulation were 10.58 and 18.80 sec., resp. BSP clearance was normal in all cases. In patients with various liver diseases (hepatitis, cirrhosis, steatosis, alcoholism, choledocholithiasis, post-hepatitis convalescence, liver metastases from various tumors), elevated BSP retention was associated with abnormal indocyanine green clearance in 22 of 28 cases; BSP levels were elevated but indocyanine green clearance was normal in 4 cases, while the reverse was true in 2 cases. None of these patients had circulatory diseases. In 26 patients with various cardiovascular diseases, the results of the 2 tests varied widely in 10 of 20 tests in patients with indocyanine green clearance of 12 sec. or over. It is suggested that the disturbances in BSP clearance in these patients resulted from extrahepatic retention or metabolism of BSP, and that the indocyanine green clearance test can serve as a method of detecting causes of error in hepatic dye-transit tests.

6328 SERUM PROTEIN IMMUNOELECTROPHORESIS IN CHRONIC LIVER DISEASES. (Fr.) Fronesci, E. (Med. Clin. & Polyclin., Bucharest, Rumania), E. Almasan and R. Tudor. Acta Gastroent. Belg. 29(10):870-878, 1966.

Of 41 patients with chronic hepatitis or cirrhosis of nonalcoholic origin, 87% showed simultaneous elevation of the γ- and α_2-globulin; the γ_1M-fraction was elevated in 70% and the γ_2-fraction in 60%. In the β-globulin fraction only the β_1A-fraction was depressed; a decrease in the α_2-fraction haptoglobin was noted in 28% In chronic hepatitis the characteristic change was an increase in γ_1M-globulin; in cirrhosis the γ_2-fraction (indicating a reaction to sclerosis) was elevated. Changes in γ_1M-globulin were parallel to those of the thymol turbidity test. The only protein considered a relatively constant measure of liver insufficiency was the Schultze seromucoid α_1.

6329 VALUE OF DETERMINATION OF ORNITHINE-CARBAMYL TRANSFERASE (OCT) IN LIVER DISEASES. DESCRIPTION OF A PERSONAL METHOD AND PRELIMINARY RESULTS. (Fr.) Rottiers, R. (Stat U., Ghent, Belgium) and L. Demeulenaere. Acta Gastroent. Belg. 29(10):821-830, 1966.

In 140 patients with jaundice resulting from hepatitis (55), cholangiopathies (38) or cirrhosis (47), serum OCT values were widely scattered, from normal (in 6, 3, and 8 cases, resp.) to extremely abnormal, in all groups. There was no relationship between serum OCT values and the type of disease. Further studies were performed in the 47 cases of cirrhosis. OCT, cholinesterase, SGOT, and SGPT values were normal in 8, 6, 2, and 15 patients, resp. Only 1 patient showed normal OCT values and elevated levels of the other enzymes, and all but 7 cases showed elevation of 3 or 4 enzymes. There was no correlation between OCT levels and levels of the other enzymes, but a good correlation between OCT levels and BSP retention values was noted in 9 of 10 cases studied. It is concluded that determination of OCT levels, being a specific test for ureogenesis, is of value in the surveillance of the evolution of cirrhosis.

6330 ORNITHINE-CARBAMYL-TRANSFERASE ACTIVITY IN THE SERUM OF HEPATOBILIAR PATIENTS. (It.) Giuditta, E. (U. Bologna, Italy) and N. Marrone. Riv. Gastroent. 17(6): 375-384, 1965.

Serum levels of ornithine-carbamyl-transferase (Demange method) were compared in 120 subjects of both sexes (age 21-45 years), of whom 80 had hepatic or biliary disease, 20 had non-hepatic diseases, and 20 were apparently health controls. Av. serum levels were 1.1 mg/0.5 ml in controls. Normal levels were observed in patients with nonhepatic diseases (gastroduodenal ulcer, gastric and intestinal carcinoma, intestinal obstruction, rectoproctitis, Crohn's disease, appendicitis, diabetes, and others), although 2 diabetic patients (1 in coma and 1 with jaundice and hepatomegaly) showed slight increase to 3 mg/0.5 ml. Highest serum levels were seen in patients with viral hepatitis with or without jaundice (11-12 mg/0.5 ml). In hepatic and biliary lithiasis,

m levels were increased only after severe
c or during the appearance of jaundice.
m levels were increased in a patient with
ary hepatic carcinoma but varied in patients
metastatic hepatic carcinoma or atrophic
hosis. It is concluded that the determina-
of serum ornithine-carbamyl-transferase
ls is a sensitive test indicating hepatic
ry.

BEHAVIOR OF PHOSPHOLIPID FRACTIONS IN
THE PLASMA OF PATIENTS WITH LIVER
ASE. (It.) Gandolfi, L. (U. Bologna, Italy),
ucci, L. Frizziero and O. Masiello. Riv.
roent. 17(6):395-409, 1965.

ma phospholipid (cephalin, lecithin,
ingomyelin, and lysolecithin) levels were
rmined by thin-layer chromatography
lified Habermann method) in 35 patients with
ous hepatic or biliary diseases. A decrease
v. plasma levels of all fractions was seen
1 patients with hepatic cirrhosis and an
ease in 4 patients with biliary cirrhosis.
gnificant increase in lecithin levels (av.
6 μg/ml) was observed in 7 patients with
ructive jaundice; increases in sphingomyelin
lysolecithin were not significant. A
ificant decrease in lysolecithin levels (av.
μg/ml) and increase in lecithin levels
56.67 μg/ml) were observed in 7 patients
acute hepatitis. Patients with hepatic
loidosis, melanosarcoma, and yellow atrophy
ved a marked decrease in lysolecithin levels;
fractions were greatly reduced in the
ient with yellow atrophy. Increased
olecithin and lecithin levels were observed
a patient with cardiac cirrhosis complicated
cholestasis. Various interpretations of
dings are discussed.

2 CHRONIC PASSIVE CONGESTION OF THE
LIVER IN MAN. ELECTRON MICROSCOPIC
DY OF CELL ATROPHY AND INTRALOBULAR FIBROSIS.
) Safran, A. P. (Mt. Sinai Sch. Med., New
k, N. Y.) and F. Schaffner. Amer. J. Path.
3):447-463, 1967.

er biopsy specimens were obtained from 3
ients with long-standing chronic passive
gestion and studied under the electron
roscope. Cells in the centrilobular zone
appeared because of atrophy, rather than
rosis. Pressure and local undernutrition
e more important than anoxia in producing
ophy. Interference with nutrition seemed to
ult from extensive fibrosis, particularly in
spaces of Disse, where blood-liver cell
hange was impaired. Fibrosis developed in
absence of necrosis, inflammation or
tular proliferation, but it was associated
h numerous fibroblasts; this indicated the
formation of fibers rather than condensation
pre-existing stroma. Canalicular dilatation
rupture were also noted, but they were
associated with cell atrophy and disruption of the liver cell plate, and not with cholestasis.

6333 CHANGES IN IMMUNE GLOBULINS IN THE COURSE OF CHRONIC HEPATITIS AND POST-HEPATITIS CIRRHOSIS (IMMUNOCHEMICAL ASPECTS, DIAGNOSTIC VALUE, AND PHYSIOPATHOLOGIC SIGNIFICANCE). (Rum.) Stoica, G. (Inst. Intern. Med., Bucharest, Rumania), V. Runcan, I. Vasiliu and C. Miron. Med. Intern. (Bucur.) 18(9):1069-1076, 1966.

Over a 3-year period, agar gel zone electrophoresis and immune electrophoresis were applied to serum protein studies on 104 subjects observed after epidemic hepatitis, 89 patients with chronic hepatitis, and 25 patients with post-hepatitis cirrhosis. Some of the findings have already been published; here the emphasis is on immune globulin changes and their clinical and physiopathologic significance within the context of the other changes in serum proteins observed during and after hepatitis. The immune electrophoresis patterns obtained were generally too similar for quantitative assessment, so only very conspicuous changes were taken into account. These included a marked increase in all 3 classes of immune globulins (especially in the γ G- and γ M-globulins) in almost all cases of chronic hepatitis and post-hepatitis cirrhosis. In contrast to certain malignant diseases, there were few instances of "dissociated," as opposed to parallel, increases, and in no case was there a decrease in any of the 3 classes. Also, a quantitative reduction in most of the α_1- and α_2-globulins was very frequently observed in severe chronic hepatitis, and almost always in post-hepatitis cirrhosis. (There was a striking contrast between the immune electrophoresis findings with respect to the α_1- and α_2-fractions and the zone electrophorogram, which usually showed an increase rather than a decrease in these fractions.) In addition to these quantitative changes, there was some evidence of qualitative changes as well, particularly in the γ M- and γ G-globulins, changes resembling those observed in Waldenström's macroglobulinemia. The diffuse nature of the hyperimmunoglobulinemia of hepatitis and the characteristic changes in the α_1- and α_2-globulins which accompany it should, however, insure against diagnostic confusion with malignant diseases of the blood and to distinguish it from other chronic inflammatory diseases (rheumatoid arthritis, lupus, etc.), in which, though the hyperimmunoglobulinemia is also diffuse, the α_1- and α_2-fractions are increased. Complete elucidation of the immunologic aspects of chronic hepatitis and post-hepatitis cirrhosis must await information about the nature of the "antiliver antibody" and the specificity of the antigens with which it reacts in serologic tests.

6334 PYOGENIC LIVER ABSCESS DUE TO MICRO-AEROPHILIC STREPTOCOCCI. (E.)

Patterson, D. K., R. S. Ozeran, G. J. Glantz, A. B. Miller and S. M. Finegold (Wadsworth VA Hosp., Los Angeles, Calif.). Ann. Surg. 165(3): 362-376, 1967.

Two cases of liver abscess due to microaerophilic streptococci are described, and 15 cases from the literature are reviewed. The true incidence of anaerobic organisms and anaerobic cocci specifically in cases of liver abscess is not known, since adequate anaerobic cultures frequently are not done. An important and often overlooked indication of anaerobic infection is putrid or foul-smelling purulent exudate. Liver photo-scanning was the most useful procedure leading to a diagnosis in the 2 cases described; it was very helpful in planning the surgical approach. Surgical drainage is the primary treatment of pyogenic liver abscess; it is best accomplished with the posterior approach in 80% of the cases. Antibiotic therapy for liver abscess in general, and for infections due to anaerobic cocci, is discussed.

6335 MODIFICATIONS OF THE BLOOD ACID-BASE EQUILIBRIUM IN HEPATIC COMA. STUDIES OF THEIR MECHANISM AND OF THE SIGNIFICANCE OF ALKALOSIS IN AMMONIA TOXICITY. (Fr.) Imler, M. (Fac. Med., Strasbourg, France), R. Bockel, W. D. Kerr, Jr. and J. Stahl. Path. Biol. (Paris) 14(23-24):1135-1144, 1966.

Respiratory alkalosis was observed during 76% of 54 episodes of hepatic precoma, in 88% of 18 episodes of hepatic coma, and in 64% of 54 patients with alcoholic cirrhosis showing no neuropsychiatric disturbances. The only factor differentiating the cirrhotic patients not in coma from precomatose patients with equivalent hyperammonemia was marked alkalosis (pH 7.5 or over), but it was not possible to differentiate comatose from precomatose stages according to the intensity of alkalosis. Metabolic alkalosis was usually not accompanied by metabolic compensation, but some patients showed metabolic compensation apparently linked with hypokalemia. Arterial hypoxemia and hyperammonemia did not seem to be the determining factors in the development of respiratory alkalosis, and alkalosis had no constant or certain beneficial effect on cerebral toxemia. Successive episodes of coma in the same patient were sometimes accompanied by about the same degree of hyperammonemia, but highly variable degrees of alkalosis.

6336 HEPATIC REPERCUSSIONS OF RESPIRATORY DISTRESS. (Fr.) Warembourg, H. (A. Calmette Hosp., Lille, France), C. Voisin, F. Guerrin, C. Wallaert, F. Wattel and B. Gosselin. Acta Gastroent. Belg. 29(12):1049-1057, 1966.

Liver function was studied in 80 emergency cases of respiratory distress; 16 patients (Group 1) were conscious with moderate hypoxia and hypercapnia, 16 showed more pronounced hypoxia and hypercapnia with some loss of consciousness (Group 2) and 48 patients had continuous CNS symptoms, decompensated hypercapnia and severe hypoxia (Group 3). Liver damage was present in nearly all cases, especially in Group 3. SGOT, SGPT, aldolase, ornithine-carbamyl transferase and LDH levels were increased in about 50% of the patients, especially in Group 3 (av. values at admission in 20 patients of Group 3 were 304, 259, 1.03, 5.8 and 1263 U, resp.). Esterified cholesterol levels were 0.8-1.2 g, but they were 0.5 g or less in some patients in Group 3 with extremely high SGOT and SGPT levels. Titers of prothrombin and the prothrombin group were over 50% in Groups 1 and 2, but below 50% in 22 patients in Group 3; coagulation factors showing particularly marked changes were Factors V and VII. Serum bilirubin and albumin levels were usually unchanged; BSP retention was abnormal i 1 of 3 cases in Group 1, 3 of 5 in Group 2, and 8 of 8 cases of Group 3 (studied at the time of admission). These liver function abnormalities were accompanied by histopathological abnormalit in 14 cases (cellular clarification and chiefly centrilobular necrosis; prolonged evolution sometimes resulted in fibrosis), but even in Group 3 the functional abnormalities regressed to normal or nearly normal after about 2 wk. of treatment. Liver damage was apparently associated only with acute respiratory decompensation of sudden onset and prolonged duration, and resembled that seen in viral or toxic hepatitis. The relationship(s) between liver function and the effects of hypoxia, hypercapnia, acidosis and, especially, secondary hemodynamic factors could not be established.

6337 LIVER MANGANESE IN HEMOCHROMATOSIS. (E.) Altstatt, L. B. (Walter Reed Army Inst. Res., Washington, D. C.), S. Pollack, M. H. Feldman, R. C. Reba and W. H. Crosby. Proc. Soc. Exp. Biol. Med. 124(2):353-355, 1967.

The conc. of Mn in liver samples from patients (20) dying with hemochromatosis was compared with the Mn conc. in liver samples from patients (20) dying of myocardial infarction. The former group were males over 35 yr. old, with liver cirrhosis, liver hemosiderosis, Fe deposition in other tissues of the body, and no history of multiple transfusions or of excess Fe ingestion; the latter group included males over 35-yr.-old, with an autopsy diagnosis of myocardial infarction, no history or autopsy findings of liver disease, no liver hemosiderosi or Fe deposition in the other tissues, and no history of excess Fe ingestion, multiple transfusions or hematologic disorders. The mean conc. of liver Mn was significantly higher in the hemochromatosis samples (4.25 μg/g dry tissue) than in liver samples free of cirrhosis and siderosis (2.13 μg/g dry tissue). A significant correlation was found between Mn and Fe content in hemochromatosis. In the age groups studied, there was no dependent relationship between age of the patient at death and Mn nc. in the liver; and in the tissues studied ere was no dependent relationship between the me the tissues were in storage and their Mn nc. It is concluded that hemochromatosis is sociated with increased liver Mn, but a causal lationship between the cirrhosis and Mn has t been established.

38 NEONATAL SERUM BILIRUBIN AND GLUCOSE-6-PHOSPHATE DEHYDROGENASE. RELATION-IP OF VARIOUS PERINATAL FACTORS TO HYPER-LIRUBINEMIA. (E.) Wolff, J. A. (630 W. 8th St., New York City), B. H. Grossman and K. ya. Amer. J. Dis. Child. 113(2):251-254, 67.

correlation was found between any one of everal perinatal factors evaluated (method of livery, complications of pregnancy and labor, dication during labor, antibiotics given, etc.) d the presence of unexplained jaundice in new-rn infants. Of 844 newborn infants, 18 (2.1%) d RBC glucose-6-phosphate dehydrogenase ficiency; all but 2 deficient subjects were of gro origin. Enzyme deficiency was not countered in any of 210 Caucasian babies. ily bilirubin values were determined for an ditional group of 119 Negro full-term male onates, in all of whom glucose-6-phosphate-hydrogenase activity was also determined. The cidence of jaundice in this series was the me in enzyme-deficient infants as in those th normal levels of RBC glucose-6-phosphate hydrogenase. For the 119 Negro full-term male wborns, the mean max. bilirubin value was 6.1 /100 ml and the mean max. bilirubin level curred at 3.3 days of age; 75% of Negro babies th bilirubin levels between 4.0 and 10.0 /100 ml did not have clinically recognizable undice. When the bilirubin level exceeded .0 mg/100 ml, almost 50% of the infants failed show a recognizable degree of jaundice.

39 BILIRUBIN NEPHROPATHY IN THE GUNN STRAIN OF RAT. (E.) Odell, G. B. Johns Hopkins U. Sch. Med., Baltimore, Md.), . C. Natzschka and G. N. B. Storey. Amer. J. ysiol. 212(4):931-938, 1967.

omozygous, jaundiced, Gunn rats were compared ith heterozygous controls for their ability to onc. urine after deprivation of water. During he last 6 hr. of a 28-hr. period of fasting and hirsting, mean urinary flow rates were 50 and 49 μliters/100 g/hr. for the heterozygous and omozygous rats, resp.; corresponding urinary smolalities were 1,909 and 815 milliosmols/kg ater. Both groups of rats excreted comparable otal solute loads, but the homozygous rats had 30% greater loss in total body wt. Losses of a in the urine of the jaundiced rats were 3 imes greater than those found for control rats. nalysis of the medullary solute composition howed that the conc. gradient for Na between he cortex and papilla in the homozygous rat was only 30 mEq/liter of tissue water. Regional analysis of the kidneys for bilirubin revealed a 100-fold greater conc. of bilirubin in the renal papilla than in the corresponding cortex. These findings suggest that bilirubin in high conc. may interfere with reabsorption of Na from the tubular fluid within the ascending limb of the loop of Henle.

6340 CONSTITUTIONAL NON-HEMOLYTIC JAUNDICE (GILBERT'S DISEASE). MORPHOLOGICAL AND FUNCTIONAL CONSIDERATIONS ON 2 CASES. (It.) Coltorti, M. (U. Naples, Italy), C. Del Vecchio-Blanco, A. Cecio and A. B. Gallo. Policlinico [Med.] 73(5):257-280, 1966.

Clinical and microscopic studies were conducted in a 13-yr.-old girl (Patient No. 1) and a 45-year-old woman (Patient No. 2) with Gilbert's disease. The Malloy-Evelyn and Eberlein tests revealed abnormally high serum bilirubin levels (almost entirely of the indirect type) in both patients, and bilirubin curve studies showed a decreased excretion of the bile pigment. However, bile pigment levels, cholangiocholecystography, laparotomy findings, routine hepatic function tests, blood tests, and RBC studies were normal in both patients. The father of Patient No. 1 had high serum bilirubin levels but to a lesser degree than the daughter; the daughter of Patient No. 2 also showed abnormal bilirubin levels. Electron microscope studies in Patient No. 1 revealed normal cell membranes but noticeable alterations of hepatocyte cytoplasm structure consisting of disruption of the endoplasmic reticulum, decrease in the number of organelles and their shift towards the perinuclear area or cell membrane. Similar studies in Patient No. 2 revealed the presence of both normal and "spongy" hepatocytes with the cell membranes of the latter type showing interruptions at the vascular pole level and consequent escape of various cytoplasm constituents into the spaces of Disse. Results suggest altered bilirubin metabolism at the level of its passage from the blood to the RBC, or at the intrahepatocyte level during transport to a conjugation site.

6341 LATE ELEVATION IN SERUM BROMSULFALEIN IN DUBIN-JOHNSON SYNDROME. A COMPARATIVE CASE STUDY. (E.) Dollinger, M. R. (Mem. Hosp. Cancer & Allied Dis., New York City) and L. L. Brandborg. Amer. J. Dig. Dis. 12(4): 413-418, 1967.

A 45-yr-old male with the Dubin-Johnson syndrome had a delayed elevation in serum BSP; this phenomenon was reported in previous patients with this syndrome. It did not occur in a patient with the closely related Rotor's syndrome, or in 4 patients with jaundice due to cirrhosis, cholangiolitic hepatitis, chronic viral hepatitis and cholestasis. This finding may be helpful in the diagnosis of the Dubin-

Johnson syndrome, especially if liver biopsy is impossible or is contraindicated; it may also assist in defining the indication for liver biopsy in family studies.

6342 ACUTE INTERMITTENT PORPHYRIA: EFFECT OF DIET AND GRISEOFULVIN. (E.) Felsher, B. F. (Walter Reed Army Inst. Res., Washington, D. C.) and A. G. Redeker. Medicine (Balt.) 46(2):217-223, 1967.

The effect of various dietary regimens and griseofulvin (2 g/day) on acute intermittent porphyria was evaluated in a group of 4 subjects which included 2 men with the disease, 1 woman with possible latent porphyria and one obese, nonporphyric male volunteer; these ranged in age from 35-47 yr. The results of this study indicated that the level of porphyrin precursor excretion in patients with acute intermittent porphyria is inversely related to the protein or carbohydrate content in the diet. In each of the 2 patients with the disease, a low-calorie, low-carbohydrate diet resulted in a marked, abrupt increase in urine pyrrole excretion. In each case, when total caloric intake, chiefly carbohydrate, was increased, there was an abrupt decrease in pyrrole excretion. When a very high-calorie, high-carbohydrate diet was given, the urine pyrrole excretion was further reduced to levels somewhat lower than those seen during a previous medium-calorie diet period. When griseofulvin was given in addition to a high-calorie, high-carbohydrate diet, there were moderate increases in urinary uroporphyrin excretion. No acute intermittent porphyria symptoms were observed, and the max. levels of uroporphyrin obtained were only 20-30% of those observed in a previous study. In 1 patient, urine porphyrin excretion was no less when griseofulvin was given during a high-calorie diet period than during a medium-calorie diet period; however, when the latter was changed to a high-calorie diet while continuing griseofulvin, a marked reduction in porphyrin excretion occurred. It is suggested that the effect of griseofulvin on prophyrin precursor synthesis is not totally abolished by a high-carbohydrate intake, but is distinctly blunted. In the obese, nonporphyric patient during a 50-day period on a 30-calorie diet, there was no increase in urinary porphobilinogen excretion, even when griseofulvin was concomitantly admin. In the female patient with possible latent porphyria, the admin. of griseofulvin with an unrestricted diet did not increase the porphobilinogen excretion. A small increase, of doubtful significance, in porphobilinogen excretion occurred after 4 days of a 400-calorie diet, but a distinct increase in urine porphobilinogen excretion to 8.7 mg/liter occurred when griseofulvin was given along with a 400-calorie diet; this was also of doubtful significance, although it is presumptive evidence of latent acute intermittent porphyria.

6343 SPLENIC PULP PRESSURE: THE EFFECT OF INJECTION OF CONTRAST MATERIAL DURIN SPLENOPORTOGRAPHY. (E.) Bjorn-Hansen, R. (U. Virginia Sch. Med., Charlottesville) and C. D. Teates. Amer. J. Roentgen. 99(3):612-61 1967.

Splenic pulp pressure was determined in 6 patients (3 with Laennec's cirrhosis with varices, and 1 each with portal vein thrombosis mild cirrhosis with a normal splenoportogram ar esophageal carcinoma with a normal splenoportogram) before and after inj. of 40 ml of 6 methylglucamine diatrizoate (renografin). In all measurements, the zero pressure level was cm H_2O. Pressure before inj. ranged from 130-590 mm H_2O, and after inj. from 270 to mor than 650 mm H_2O. Pressure 10 min. after inj., determined in 4, ranged from 250-650 mm H_2O. Elevation of splenic pulp pressure may be sufficient to cause an erroneous diagnosis of portal hypertension if pressure is not measure before inj.; it is therefore suggested that pressure should always be measured before inj. of contrast material.

6344 PLEA FOR EXACT HEPATIC SEGMENTATION AND ANATOMICAL PRECISION IN LIVER RESECTION. PARTIAL CLAMPING OF THE HEPATIC PEDICLE. (Fr.) Couinaud, C. (Saint Antoine Hosp., Paris, France). Presse Med. 75(55): 2849-2852, 1966.

A critical survey of recent studies on liver resection revealed an anatomical error, the description of the left lobe as a portal entit with 2 segments separated by a sagittal scissu The left lobe is, in fact, a suprahepatic entity (the region of the left suprahepatic vein), separated from the remainder of the liv by the "umbilical" (left suprahepatic) scissur The left liver is divided into 2 sectors from the point of view of the portal circulation. Clamping the hepatic pedicle for not more than 10-15 min. (shorter in the presence of parench failure) will permit a bloodless operative field, but differential clamping of 1 or sever sectorial pedicles is tolerated much longer. In a man with cholangioma of Segments V and VI clamping of the right hepatic pedicle only for a total ischemic period of 6 min. permitted bloodless removal of the involved segments. Partial clamping of this type is recommended t reduce the mortality rate among patients undergoing partial hepatectomy.

6345 PROLONGED SURVIVALS AFTER PARTIAL HEPATECTOMIES AND SECOND-LOOK PROCEDURES FOR PRIMARY AND SECONDARY CARCINOMA OF THE LIVER. (E.) Friesen, S. R. (U. Kansas Sch. Med., Kansas City), C. A. Hardin and C. F Kittle. Surgery 61(2):203-209, 1967.

Several factors which favor successful partial hepatic resection are discussed; these include r methods of diagnosis (including alkaline sphatase determinations, protein electrophoresis new radiologic technics), refinements of rative technic and greater understanding of regenerative power of the liver. Cases are ulated to illustrate long-term survivors of ial hepatic resection of primary and ndary tumors of the liver. Surgical sions, made safer by anatomic studies and by iologic support of the liver, are apparently thwhile for those patients with primary or ndary liver carcinomas. The most promising ture of management, leading to greater success more long-term survivors, is a second-look gram for the detection of lesions, while they small and localized, in asymptomatic patients.

5 CYTOLOGIC DIAGNOSIS OF CANCER FROM ASPIRATED MATERIAL OBTAINED AT LIVER

PSY. (E.) Sherlock, P. (Cornell U. Med. ., New York City), Y. S. Kim and L. G. Koss. . *J*. *Dig*. *Dis*. 12(4):396-402, 1967.

rocedure is described whereby a single liver cture provides material for both cytologic histologic preparations. A total of 62 ients with various diseases of the liver uiring diagnostic liver biopsy were studied. of 13 patients with metastatic carcinoma in liver diagnosed histologically had malignant ls in the cytologic preparation. An itional 2 patients with histologically normal er biopsy specimens had malignant cells on ologic preparation. In addition to diagnosis liver neoplasia, such other diseases as osiderosis, inflammatory processes and fatty iltration were demonstrated by examination of cytologic preparation. A greater sampling the liver is accomplished by microscopically mining material which is normally discarded. results of this investigation demonstrate value of the cytologic examination of irated material and touch preparations from er biopsy specimens in the diagnosis of ors and other diseases of the liver.

7 HISTAMINE FORMATION IN RATS BEARING THE WALKER MAMMARY CARCINOSARCOMA.

) Johnston, M. (U. Lund, Sweden). *erientia* 23(2):152-154, 1967.

lt female rats, Sprague-Dawley and Institute-d, were implanted with Walker mammary cinosarcoma, and the rate of histamine forma-n *in vitro* by the tumor and by the liver was sured for control and tumor-bearing animals. addition, the effect of the enzyme inhibitors ethylhistidine and α-methyldihydroxyphenyl-nine on tumor and liver tissue was investi-ed *in vitro*. Urinary free histamine excretion reased with tumor growth. The rate of tamine formation *in vitro* in liver tissue of or-bearing rats was very much higher than in -tumor bearing controls. The effects of the pounds α-methyl histidine and α-methyldihydroxyphenylalanine on the rate of histamine formation in tumor tissue and liver of the tumor-bearing host were different; in both liver and tumor, the former compound produced 70-90% inhibition of enzyme (histidine decarboxylase) activity, while the latter had almost no inhibitory effect. In an experiment on parabiotic rats (female littermates, 1 of which was tumor-bearing), there was a general elevation of the histamine-forming capacity in many tissues, including the liver. The unusually high excretion of histamine in urine of female rats with Walker mammary carcinosarcoma can be explained by the ability of the tumor itself to form histamine, and also by the increased capacity of the liver in this respect. From the parabiotic rat experiments, it appears that the histamine-forming capacity of several tissues, including the liver, may become elevated and that a blood-borne factor is involved. Observations of high histamine-forming capacity in tumor and enlarged liver tissue support the concept that there is a relationship between high rates of histamine formation and certain types of rapid tissue growth.

6348 EXPERIMENTAL STUDIES OF FACTORS INFLUENCING HEPATIC METASTASES.

XVIII. SIGNIFICANCE OF TRAPPED TUMOR CELLS. (E.) Fisher, B. (U. Pittsburgh Sch. Med., Pa.) and E. R. Fisher. *Proc*. *Soc*. *Exp*. *Biol*. *Med*. 124(3):881-883, 1967.

There was no increase in numbers of intraportally inj. ^{51}Cr-labeled Walker tumor cells in the livers of rats that were subjected to partial hepatectomy, inj. of dextran, hepatic manipulation, reticuloendothelial blockade, high (30%) fat, choline-free diet or caval constriction. These findings indicate that augmentation of hepatic metastases produced by these modalities in this model system is related to their metabolic or biologic ("soil") rather than mechanical influences on hepatic-tumor cell relationships.

6349 PRIMARY HEPATIC STEATOSIS AS A METABOLIC CHANGE IN EARLY DIABETES.

(E. & It.) Knick, B. (U. Clin., Mainz, Germany). *Acta* *Diabet*. *Latin*. 3(2):224-234, 1966.

Diabetes detection tests were conducted in 104 patients (all over 40 yr. of age) with first stage fatty liver of a non-alcoholic etiology and results were compared with healthy subjects and other groups suspected of diabetes. Employing the tolbutamide test, pathological findings were obtained in the fatty liver patient group as well as in the control group of healthy subjects. Primary hepatic steatosis of early diabetes was related 65-70% of the time to excessive body wt. Abnormal results were observed also in the groups of mothers with large babies (birth wt. over 4500 g) and close relatives of diabetic patients. These results suggest that such abnormal results indicate the presence of latent or asymptomatic diabetes mellitus. Fasting values were higher in the fatty liver patient group than in metabolically normal subjects when serum insulin-like activity was assessed. Following tolbutamide or glucose stimulation, insulin reserve analysis showed delayed insulin secretion with high fasting values (a high serum insulin-like activity) in the fatty liver patient group. It is concluded that hepatic steatosis is an abnormal manifestation of an underlying lipogenic insulin effect on the liver and may well represent a metabolic change preceding asymptomatic diabetes.

6350 STEATONECROSIS--MALLORY BODY TYPE. (E.) Harinasuta, U. (VA Hosp., Washington, D. C.), B. Chomet, K. Ishak and H. J. Zimmerman. Medicine (Balt.) 46(2):141-162, 1967.

A study of the clinical, biochemical and histologic features of steatonecrosis (Mallory body type) is presented, based upon clinical records and liver sections of 175 patients whose livers showed Mallory bodies. Characteristic histologic findings of necrosis, fatty metamorphosis and Mallory bodies may occur with or without cirrhosis. This syndrome apparently represents a form of acute metabolic failure of the liver resulting from severe, prolonged alcoholism and malnutrition. It is a complication of fatty metamorphosis or of developing cirrhosis, which most frequently affects relatively young or middle-aged patients, and is usually characterized by jaundice and fever, with or without coma, gastrointestinal hemorrhage or ascites. Portal hypertension, spider nevi, coagulation defects and testicular atrophy occur frequently. Impaired BSP excretion, elevated alkaline phosphatase levels, hyperbilirubinemia and increased values of SGOT occur in most patients. Values for SGOT exceed those of SGPT. Hypoalbuminemia and hyperglobulinemia frequently occur. The prognosis is grave in the deeply jaundiced, azotemic, hypothrombinemic patient with steatonecrosis. Death is usually due to hepatic coma, gastrointestinal hemorrhage or intercurrent infection; sudden death, of unknown specific cause, has an appreciable incidence. In the moderately jaundiced patient, whose blood urea nitrogen level is not elevated and whose prothrombin time is only slightly prolonged, prognosis is usually good. Typical histologic abnormalities may occur in patients who are anicteric and whose bilirubin levels are only slightly elevated. Conversion of mild to severe steatonecrosis possibly may be induced by associated pancreatitis and other organic sequelae of alcoholism, infection, accidents of cirrhosis (such as gastrointestinal hemorrhage), or other intercurrent circumstances.

6351 CLINICAL IMPLICATIONS OF FATTY LIVER. (E.) Palmer, E. D. (VA Hosp., E. Orange, N. J.). GP 35(4):125-131, 1967.

Simple nutritional fatty liver was diagnosed biopsy in 131 patients (119 male and 12 femal who were subsequently treated as outpatients up to 7 yr. (approx. 25% for over 4 yr.). Heavy alcohol ingestion over long periods was related by 98 patients. Diagnostic procedure included single or multiple needle biopsy of liver, upper gastrointestinal studies and sir or multiple esophagoscopy. Only 11 patients sought medical assistance for conditions rela to liver disease, including variceal bleeding resulting in hematemesis (5), jaundice (3), simple recurrent dyspepsia (2) and chronic ri upper quadrant pain (1). The remaining 120 patients were discovered to have hepatomegaly either during hospitalization for other complaints (77) or routine physical examinati (43). Of the 131 patients, 122 presented hepatomegaly. Other gastrointestinal conditi included duodenal ulcer (24), hiatus hernia subacute esophagitis (15), gallstones (7), ga tric ulcer (4), diverticulosis (3), post-gastrectomy state (3) and chronic relapsing pancreatitis (9). Esophageal varices were found in 54 patients (11 showed hemorrhage). Therapy consisted of abstinence of alcohol, reduction in obese patients, appropriate diet regimen and control of diabetes. Most improv ment was subjective in character with no pat showing liver fat clearance. No patient died during observations or progressed to cirrhos Varices appeared unchanged in 8 patients whe observed by successive esophagoscopy (up to yr.) while the condition worsened in 5 patie

6352 FATTY LIVER IN THE RAT AFTER PROLO INTAKE OF ETHANOL WITH A NUTRITION ADEQUATE NEW LIQUID DIET. (E.) DeCarli, L. (Bellevue Hosp., New York City) and C. S. Li J. Nutr. 91(3)(Pt. 1):331-336, 1967.

Male Sprague-Dawley rats were fed liquid die containing 18% of calories as casein, supplemented with methionine (0.3 mg/kcalorie) and cystine (0.5 mg/kcalorie), choline (0.25 mg/kcalorie), fat (35% of total calories), adeq minerals and vitamins and, in the control di 47% of the calories as carbohydrate. A litt mate of each control rat was pair-fed with t same diet in which carbohydrate had been isocalorically replaced with alcohol to the extent of 36% of the total calories. This dietary regimen assured continued growth in animals and normal liver in the controls, wh in the rats fed with alcohol, fatty liver developed, which was evident both morphologi and on chemical analysis; after 24 days of alcohol, hepatic triglycerides had increased the av. 6-fold and cholesterol esters 5-fold compared with those of the controls. These results show that prolonged alcohol intake c produce a fatty liver even when admin. with diet with nutritionally adequate content of tein, vitamins and minerals, and an amount o fat less than that of the av. American diet.

AUXILIARY LIVER TRANSPLANTATION IN DOGS WITH ARTERIALIZATION OF THE POR- EIN. PRELIMINARY COMMUNICATION. (E.) s, G. L. (Yale U., New Haven, Conn.), D. eeckeren and I. Matano. Int. Surg. 47(3): 23, 1967.

dogs in which auxiliary liver homografts performed and the portal vein was perfused mixed arterial and venous blood, 3 dogs ved more than 7 days while 4 dogs survived ays and 7 dogs succumbed during or iately after transplantation. Interruption e host's portal circulation was precluded is simplified method by inserting the homo- into the systemic circulation (an arterio- s fistula between the right femoral vessels erformed 4-5 days previously). Dogs ving less than 1 day died from hepatic rhage or portal vein hypertension. In dogs ving over 7 days, histologic examination at s showed focal fibrosis without cirrhosis ith minimal necrosis. In addition, prominent lar proliferation, canalicular cholestasis, al round cell infiltration and no evidence jection were observed in this same group. f auxiliary livers were 30-85 g greater than of the host liver in 4 dogs and 20 g less dog in the max. survivor group.

HOMOTRANSPLANTATION OF THE CANINE LIVER AFTER HYPOTHERMIC PERFUSION OF DURATION. (E.) Kestens, P. J. (U. Louvain, um), P. Mikaeloff, J. J. Haxhe, G. Dureau, exandre, J. P. Rassat, J. Cuilleret, A. un, M. Dubernard, J. Descotes and J. Morelle. Soc. Int. Chir. 25(6):647-659, 1966.

topic homotransplantation (12) in the dog ccomplished following hypothermic perfusion ng between 90 and 325 min. (12-18°C chymal temperature, with 10°C being main- d during the last 10 min. of perfusion). g perfusion, blood flow as well as portal rterial pressures were normal as also was pH. SGOT and SGPT levels increased some- whereas LDH was constant and normal during sion. A slight reduction in plasma K s was observed. Gross appearance of the during perfusion was normal in all except es. Av. duration of venous bypass was 20 with the mean period of hepatic anoxia being n. After anastomoses most dogs were in health with elevated blood ammonia levels sed after transplantation. Transaminase DH values were slightly increased before plantation, but stabilized after 1 hr. wing grafting. BSP retention ranged from % in 3 dogs after grafting (irreversible nolysis in 1 dog resulting in fatal rhage). During early postoperative period, ased transaminase levels (a mean SGOT and value of 102 and 165, resp., after 4 days) noted along with normal bilirubin and LDH s. Survival times included periods ding 5 days (9 dogs), exceeding 10 days (7 dogs) and 4 dogs alive after 50, 17, 14 and 12 days, resp. The success of this study probably indicates that maintenance of viability of a cadaver liver during preparation of recipient patient can be achieved.

6355 HEPATIC HETEROTRANSPLANTATION. (E.) Arena, A. J. (Albany Med. Coll., N. Y.), J. H. Carter, J. R. Cooper, J. Margulies and C. S. Welch. Bull. Soc. Int. Chir. 25(6): 660-670, 1966.

Hepatic transplants of cat livers to dogs were divided into 4 experimental categories, including 26 heterotopic transplants with autologous hepatectomy (Group 1); 2 orthotopic transplants (Group 2); 7 heterotopic transplants without autologous hepatectomy (Group 3) and 3 heterotopic transplants with delayed re-exploration (Group 4). After completion of transplantation, a dextrose soln. was continuously given until death ensued. Postoperatively, prolonged clotting times with unmanageable rapid lysis were frequently observed in the 15 survivors from Group 1 as well as elevated blood ammonia and transaminase levels. Nine dogs showed a hemorrhagic diathesis at autopsy, while the cause of death was not apparent in the remaining 6 dogs. Most transplanted livers were dark in color and congested, with all anastomoses being patent. In Group 2 dogs, 1 died during surgery from portal bed block, while the second dog, which died 3 hr. postoperatively, manifested a hemorrhagic diathesis at autopsy. The 4 dogs from Group 3 who survived for more than 24 hr. (36 hr., 9 days, 12 days and 14 days) finally succumbed with the latter 3 maintaining good activity until 1-2 days prior to death. Daily biliary drainage (initially hemorrhagic) ranged from 5-20 ml over the 5-6 day period. Normal clotting times as well as serum bilirubin and blood ammonia were not abnormal. Only 1 dog from Group 4 was subjected to later hepatectomy (on fourth post-transplant day) and died 10 hr. later following a course characterized by loss of eye and swallowing reflexes, coma, and jerking movements of the extremities. No prolongation of clotting time or hemorrhage was observed in this group.

6356 ACTIVE SENSITIZATION FROM HETEROLOGOUS LIVER PERFUSION. (E.) Bibler, D. D., Jr. (U. Washington Sch. Med., Seattle), R. E. Condon and L. M. Nyhus. Bull. Soc. Int. Chir. 25(6):671-679, 1966.

Bovine and porcine livers were perfused with human blood obtained from open heart procedures for 5.5 hr. Blood pressure during perfusion was maintained at normal levels by varying the flow rate, and plasma samples which were obtained both before and after perfusion were evaluated by immunoelectrophoresis. All perfusions demonstrated the existence of heterologous proteins. Following recovery from hepatic insufficiency (one-stage Eck fistulae) and 70% hepatectomy, the blood from these 4 dogs and 2 normal control dogs was perfused through a bovine liver for 2 hr. Bovine protein was demonstrated in every sample of blood after perfusion. Bovine plasma (with protein) was inj. i.v. 11-35 days after perfusion. Two dogs in hepatic insufficiency showed anaphylactic reactions within 5-7 min. after inj. with one succumbing 12 hr. later and the other recovering fully in 1 hr. In the former dog, moderate congestion of the liver and lungs was shown at autopsy. No reaction was observed in the other 2 dogs (1 control, and 1 with hepatic insufficiency). A second perfusion, 28 days after the first, in a control resulted in death in 18 hr. with no apparent anaphylaxis. At autopsy, focal hemorrhage of the liver in this control was observed along with moderate central and portal vein necrosis, with slight cellular necrosis noted at light microscopy. Areas of atelectasis were also observed. Marked fatty infiltration was seen in the livers of dogs with hepatic insufficiency. Employment of heterologous liver perfusion in patients can result in sensitization, with the possibility of anaphylaxis following a second perfusion after a period of latency.

6357 ORTHOTOPIC AUTOTRANSPLANTATION AND ALLOTRANSPLANTATION OF THE LIVER: FUNCTIONAL AND STRUCTURAL PATTERNS IN THE DOG. (E.) Stuart, F. P. (Harvard Med. Sch., Boston, Mass.), E. Torres, W. J. Hester, G. J. Dammin and F. D. Moore. Ann. Surg. 165(3):325-340, 1967.

A technic of orthotopic hepatic allotransplantation in dogs is described in detail; principal features of this method are a temporary "Y" shunt for hepatic venous bypass and anastomosis of the recipient renal artery to the donor celiac artery. Hepatic autotransplantation, using a modification of the allotransplantation procedure, was done on 4 dogs; only minor functional and structural changes were noted in the autotransplanted livers. Azathioprine, given to 6 normal dogs, caused only minor adverse effects on the liver. Orthotopic allotransplantation of the liver was performed on 52 dogs. Four immunosuppressive protocols were tested; the first, actinomycin-C alone, did not prolong survival of the graft. Three protocols using various combinations of azathioprine, actinomycin C and local X-irradiation of the liver, were equally effective in their modest ability to prolong graft survival. Six dogs survived more than 50 days; the longest survivor lived 88 days. All 6 dogs were undergoing slow hepatic rejection and had upper gastrointestinal ulceration at the time of death; massive hemorrhage from upper gastrointestinal ulcers was the immediate cause of death in 5 of the six dogs. Ulceration was prevented by subtotal gastric resection, but not by vagotomy and pyloroplasty. It is suggested that the ulceration was acid-peptic in nature and may have been due to an humoral mechanism associated with hepatic rejection.

6358 ASANGUINOUS HYPOTHERMIC LIVER PERFUSION IN DOGS. (E.) Ono, H. (U. California Sch. Med., Los Angeles), G. D. Buckberg and W. P. Longmire, Jr. J. Surg. Res. 7(4):152-159, 1967.

An original, consistently reproducible and simplified technic for the isolation and perfusion of the canine liver in vivo was developed after experimentation on more than 60 dogs. By means of an abdominal approach, hepatic outflow was isolated by use of an intracaval shunt and creation of a chamber containing pure hepatic effluent surrounding the shunt. The necessity of extracorporeal circulation and heparinization was eliminated. This procedure is free from systemic admixture, as shown by BSP determination. Regional hepatic hypothermia is maintained at 14-16°C without systemic hypothermia. Contamination with blood is reduced to less than 1 ml/min. (the effluent hematocrit is consistently less than 1%) after the washout. Hepatic outflow block was not seen either during or after perfusion. Hypotension did not follow revascularization in perfusion lasting up to 90 min. Mild hypotension occurred after perfusions of up to 180 min., but it was spontaneously reversed without the need for vasopressors. Altogether, 11 of 15 dogs survived after being perfused between 60 and 90 min.; 3 of 6 dogs survived after being perfused 120 min. Death could not be attributed to hepatic failure in dogs perfused for longer periods of time.

6359 OBSERVATIONS ON THE EFFECTS OF GLYCEROL IN THE COLD STORAGE OF THE CANINE LIVER. (E.) Moss, G. S. (U. Manchester England), P. C. Reed and A. G. Riddell. J. Surg. Res. 6(4):147-151, 1966.

The protective role of glycerol in the whole-organ cold storage of the canine liver is reported. Following liver removal, the organ was infused with increasing conc. of glycerol at 5°C in 3 stages (500 ml of 10%, 20% and 33% glycerol soln.) and sealed in a plastic bag containing 33% glycerol and then stored at -20°C for 24 hr.-2 wk. Final thawing involved placement in a domestic regrigerator until -13°C was attained which was then followed by temperature infusion and gradual 'deglycerolization' using decreasing conc. of glycerol. These specimens were divided into 2 groups; 1) placement in an isolated pump oxygenator circuit and perfused, or 2) transplantation into the right paracolic gutter of healthy dogs (9 transplants). A control series of 4 livers was established for comparative purposes. In the isolated perfusion series, significant O_2 uptake (less than controls) was

erved; impaired BSP clearance and unsatis-
:tory flow rates however for less than 1 hr.
3 specimens. In 3 livers of the transplant
ries, BSP uptake measured after 1 hr. of cross-
rculation (portal vein-to-portal vein
astomoses performed) were poor, but signifi-
nt, in 2 dogs and absent in the other 1. None
the 6 dogs with end-to-side anastomosis
rvived. Other post-transplant phenomena
cluded a deep-red coloration and oozing from
ver surface, clotting disturbance, leakage
om suture lines, gross hemolysis, metabolic
idosis and reduction in fibrinogen levels.
stologically the most important change due to
ycerolization was widening of the sinusoids,
pecially after, complete freezing, which was
solved after thawing and 'deglycerolization'
less irretrievable damage had occurred.
cuolization of the cytoplasm increased with
oling and decreased again on warming. Many
clei became pyknotic after freezing. The
caffold' pattern of the cell reticulum was
eatly damaged in a few cases. During periods
cold storage, a gradual decrease in glycogen
ntent was indicated by serial section studies.

60 A METHOD FOR COLD PRESERVATION OF LIVER. (E.) Brown, H. (Harvard Med.
h., Boston, Mass.), J. Patel, D. W. Blair,
M. Barsamian and W. V. McDermott, Jr. J.
rg. Res. 7(2):71-77, 1967.

nine liver dehydrated 5%-36% was stored for as
ng as 45 days at -6°C immersed in either 2 M
ycerol or 2 M dimethylsulfoxide soln., without
eezing, by a method termed "supercooling".
e activity of 4 urea cycle enzymes studied
rginase, carbamyl phosphate synthetase,
rnithine transcarbamylase, argininosuccinase)
emained normal during this period. In 7
periments, livers preserved as long as 5 days
ere heterotopically transplanted and survived
-6 additional days, as judged by survival of
e recipient, patency of blood vessels and
ross appearance. Technical difficulties and
roblems with early transplant rejection were
ncountered; nevertheless, it is concluded that
is method (or some refinement of it) will
ventually offer an experimental means for pro-
onged liver preservation.

361 THE FUNCTIONAL CAPACITY OF PIG LIVER PERFUSED WITH HUMAN BLOOD. (Ger.)
oeckl, O. (Salzburg Hosp., Austria), E. Hell,
. Zimmermann and H. Schroll. Wien. Klin. Wschr.
9(1):17-19, 1967.

ivers of Minnesota dwarf pigs (17-45 kg) were
xcised, the cystic duct ligated, the bile duct,
he inferior vena cava, and the hepatic artery
r the portal vein catheterized, after inj. of
0,000 U of heparin. The livers weighed
30-1040 g. The vascular system was washed out
ith saline at 4°C containing 2500 U heparin/
00 ml for 10-20 min. until the liver was cooled and completely freed of blood. Placed in a heart-lung apparatus with regulated temperature, the liver was perfused with heparinized human blood (supplied via the portal vein or hepatic artery and drained through the inferior vena cava). During the entire perfusion continuing blood gas analyses, pH and pressure measurements were made; adjustments kept these parameters within normal range. The usual duration of perfusion was 3 hr. BSP test, blood picture, hematocrit, electrolyte determination, SGPT and LDH measurements were made; the vol. of bile was measured. Also measured was the clearance of 131I-Bengalrose. In the case of 1 animal a SBP test was made prior to liver excision, after excision during perfusion with autologous blood and then with heterologous blood. The vol. of bile was measured for 3 hr. during autologous and heterologous perfusion. The BSP test showed dye retention of 4.8% after 60 min. in vivo, 43% in autologous, and 63% in heterologous perfusion. Bile production was less than half during heterologous as compared to autologous perfusion. RBC count, hemoglobin conc., and hematocrit sharply decreased, whereas serum enzymes and hemolysis increased during perfusion with human blood. The liver excretion of 131I-rose bengal showed marked impairment after the first hr. of perfusion. Pig liver, perfused with human blood under controlled normal conditions, retains its functional capacity for 3 hr. at most. In principle it is possible to use the pig liver for the removal of impurities from human blood after clarification of technical and clinical details.

6362 CONTINUOUS MONITORING OF TRANSHEPATIC VASCULAR RESISTANCE IN THE ISOLATED PERFUSED EX-VIVO PORCINE LIVER: EXPERIMENTAL AND CLINICAL METHODS. (E.) Norman, J. C. (Harvard Med. Sch., Boston, Mass.), W. J. Robinson, E. J. McDonald and W. V. McDermott, Jr. Med. Res. Engineer. 6(1):17-19, 1967.

Technics of continuous visual monitoring of relative transhepatic resistance in isolated perfused ex-vivo porcine liver preparations are described. In experimental systems, oxygenated blood is achieved by recirculating blood from the outflow channel through a column bubble oxygenator, whereas, in clinical setups, arterial blood from the patient is gravity-fed to the liver specimen and then pumped through an extracorporeal filter back to the patient. Effective transhepatic vascular resistance is represented by a running quotient which issues from a computer which has accepted an amplified transhepatic pressure gradient (delta P). This gradient results from continuous subtracting of outflow from inflow pressure in mm Hg by a single differential pressure transducer. Connected with the computer is a flowmeter which in turn is connected in series with either the inflow line from the disposable oxygenator or with the patient's brachial artery. In clinical trials, during acute hepatic failure, artificially induced increases and decreases in resistance resulted in corresponding alternate increases and decreases in flow and small alternate increases and decreases in transhepatic pressure gradient. Residual hypothermia (porcine liver was subjected to hypothermia to preserve viability during periods of total ischemia) was indicated by a monitored increase in resistance. Increased resistance and decreased gravity flow rates were observed in both experimental and clinical acidosis of perfusates (reversed by pH maintenance between 7.35 and 7.4). Gradual increase in resistance resulted from both experimental and clinical increase in length of perfusion time. However, no significant increases were noted after 9 hr. of clinical perfusion in which rates exceeding 1,200 ml/min. were accepted by the porcine liver.

6363 OBSERVATIONS AND MANAGEMENT AFTER HEPATIC ARTERY LIGATION. (E.) Mays, E. T. (U. Louisville Sch. Med., Ky.). Surg. Gynec. Obstet. 124(4):801-807, 1967.

A 53-yr.-old Caucasian male presented with multiple (15-20) self-inflicted abdominal stab wounds (most of which were superficial). At laparotomy, a clean sharp through-and-through stab wound of the left lobe of the liver was noted just a few cm to the left of the falciform ligament, on the inferior border; the wound of exit was in the region where the left hepatic artery entered the hilum of the liver. The latter artery was dissected free and ligated close to its entrance into the liver. Except for a brief bout of delirium tremens, the postoperative recovery of this patient was uneventful. This patient was unique from 3 standpoints: 1) the hepatic artery was intentionally ligated and liver function was normal; 2) there was an absence of a state of shock; and 3) there was a lack of damage to liver cells or previous hepatic dysfunction. Blood chemical studies showed a mild and temporary depression of the ability of the liver cells to synthesize protein. SGOT decreased from 60 U/ml at 5 days after operation to 19 U/ml at 43 days; SGPT decreased from 36 U/ml to 20 U/ml. Cephalin flocculation was 2+ at day 5, 0 at day 12 and a trace at day 25. Total protein increased from 5.9 g% at day 5 to 7.3 g% at day 43. Bilirubin decreased from 1.4 mg% at day 5 to 0.65 mg% at day 43. Detoxification, excretory function and carbohydrate metabolism appeared unchanged. Liver scintiscans revealed a persistent decrease in radioactive Au uptake in the left lobe; since the same decrease in uptake was observed at 6 wk. after ligation and during this time liver function studies had greatly improved, it probably represented a permanent decrease in the amount of arterial blood flow to this lobe rather than cellular dysfunction. In this patient, survival and hepatocellular viability was more dependent upon portal venous flow than on collateral arterial flow. This and other studies signify that the concept of interrupting arterial flow in man is undergoing a gradual change.

6364 THE EFFECT OF INTRAHEPATIC BILE STASIS, CATECHOLAMINES AND HYPERTENSION ON THE HEPATIC ARTERY BLOOD FLOW. (E.) Kubiak, J. (Med. Acad., Warsaw), J. Litwin, H. Rykowski, L. Bielecki and M. Simoni. Bull. P Med. Sci. Hist. 10(1):28-32, 1967.

The effect of acute bile stasis and admin. of catecholamines and hypertensin on hepatic arterial blood flow was studied in 12 anesthet dogs; systemic arterial blood pressure, centra venous blood pressure and hepatic arterial bl flow were registered. Peripheral resistance obtained from the quotient of the mean arteri systemic blood pressure and blood flow in the hepatic artery. In controls, blood flow was 44.1 ml/min. and peripheral vascular resistan was 2.05 peripheral resistance U. Following ligation of the common bile duct, these parameters were determined after 1, 2, 3, 4 and 9 days. Blood flow in the hepatic artery decreased to 15.1 ml/min.; vascular resistance the hepatic artery increased to 10.9 periphera resistance U. Decrease in blood flow in the hepatic artery during acute bile stasis was caused by 2 factors: 1) mechanical pressure exerted on the arteries by the dilated bile ducts, and 2) the effect of some vasoconstrictive substances (such as dehydrocholic acid) absorbed from the bile. Histological study of liver sections revealed that complete ligatio of the common bile duct produced a temporary hyperemia, a stasis of the bile and then a proliferation of connective tissue in the live parenchyma. Catecholamines and hypertensin (b increasing systemic arterial blood pressure) increased flow in the hepatic artery and at th same time decreased the hepatic blood flow (by their direct vasoconstrictive effect) in controls and in experimental dogs with bile stasi Under these conditions, hypertensin elevated the systemic arterial pressure, but this was followed by a decrease in the hepatic arterial blood flow. This fact should be considered before use of hypertensin in cases of frank liver pathology.

6365 TRANSUMBILICAL PORTAL HEPATOGRAPHY, SIGNIFICANT ADJUNCT IN THE INVESTIGATION OF LIVER DISEASE. (E.) Piccone, V. A. (VA Hosp., Brooklyn, N. Y.), H. H. LeVeen, J. White, G. B. Skinner and L. D. MacLean. Surge 61(3):333-346, 1967.

Portal hepatography, with an indwelling catheter placed directly in the portal vein by way of the umbilical vein, was performed on 60 patients. A consistently high-quality contras visualization of the portal vasculature was provided. Selective lobar angiography, 2-plan visualization and serial films provided significant, precise information about the

tion and size of space-occupying lesions
the dynamics of portal and collateral
ulation. Lesions as small as 1.0 cm in
eter were readily located; the collateral
ulation in portal hypertension was vividly
mented. Transumbilical portal hepatography
valuable in the recognition of intrahepatic
ons, in the differentiation of extrahepatic
ons contiguous to the liver, in the
nstration of vascular anomalies and in
rate placement of the needle for liver
sy. There was little morbidity and no deaths.
opportunity for concomitant liver biopsy
serial portal manometry, together with the
tanding radiologic clarity itself, demon-
te that this procedure is a significantly
rior method in the investigation of liver
ase.

COMPLIANCE OF THE LIVER. (E.) Wood,
W. (U. Kentucky Med. Sch., Lexington),
ait and B. Eiseman. Surgery 61(3):407-416,
.

effect of altering both perfusion pressure
hepatic venous (outflow) pressure was
uated as they affect flow and the wt. of the
ivo pig liver. Critical closing pressure of
liver under these perfusion conditions was
cm H_2O. The anticipated sigmoid
tionship between perfusion pressure and flow,
h has a plateau at approx. 200 cm H_2O
usion pressure, was observed. The pig
r will hold more than twice (209%) its
y wt. of blood when fully engorged. In-
se of the hepatic venous pressure caused
ention of the liver in proportion to the
low pressure within physiologic perfusion
sures. Compliance was expressed numerically
he increase in liver vol./10 mm Hg increase
epatic venous pressure. Normal pig liver
ed max. compliance with resistance incre-
s at low hepatic venous pressures.
liance progressively decreased as the liver
me max. engorged at 30 mm Hg hepatic venous
sure. Analogous to the pressure-vol.
tionships of the lung, hysteresis loops have
described for the normal liver. The
ications of hepatic compliance as it may
r function in the cirrhotic liver are
ussed.

7 HEPATIC PORTOGRAPHY BY DIRECT
CATHETERIZATION OF THE PORTAL VEIN
OUGH THE ROUND LIGAMENT OF THE LIVER
GAMENTUM TERES). (E.) Chiandussi, L. (U.
in, Italy), G. Juliani, F. Greco, D. Cravero,
Sardi and G. Toscano. Amer. J. Roentgen.
3):625-628, 1967.

atic portography by direct catheterization of
portal vein through the round ligament of
liver (ligamentum teres) was successfully
formed in 2 of 3 subjects with a normal liver
in 7 of 8 patients with well-compensated liver cirrhosis (in 1 of 8, cirrhosis was associated with a primary tumor of the left lobe of the liver), with no complications being noted. The whole procedure lasted 20-30 min., unless various portal vein parameters were determined. Direct catheterization of the portal vein allows direct measurement of the portal pressure, determination of portal vein blood flow separately from flow of the hepatic artery, direct portography and biochemical assay of portal blood. This procedure appears to be safer than splenoportography and is the technic of choice in patients with suspected portal hypertension and splenectomy, with thrombosis of the splenic vein and with incomplete visualization of the portal intrahepatic vascular tree of the left lobe. It is helpful in interpreting false images of portal vein thrombosis in patients with portal hypertension and large gastro-esophageal collateral circulation. Extremely clear visualization of the networks of the smallest intrahepatic branches of the portal vein and an excellent late hepatographic effect can be obtained by direct portography. This technic is more difficult to perform than other procedures, the splenic vein and the portosystemic collaterals are not demonstrated, and the main portal trunk is only partially visualized. However, in selected cases the advantages of this procedure outweigh its limitations.

6368 CENTRAL SPLENORENAL SHUNT IN THE TREATMENT OF PORTAL HYPERTENSION. (Fr.) Bismuth, H. (Bichat Hosp., Paris), J. Moreaux and J. Hepp. Ann. Chir. 20(25-26): 1441-1445, 1966.

Splenorenal anastomosis was performed in 30 patients with extrahepatic (5) or intrahepatic blockage (25; 22 with cirrhosis). On 5 occasions the procedure was performed for emergency correction of hemorrhage; 2 patients died after 1 or 10 days. In 4 patients with portal thrombosis, there were no postoperative deaths or recurrent hemorrhages; in the other group of 21 patients there was 1 operative death (Gram-negative septicemia) within 1 mo. and 2 patients (both with cirrhosis, ascites and encephalopathy at admission) died 3-4 mo. after surgery. In the surviving patients the follow-up time was too short for adequate evaluation (2-22 mo., av. 1 yr.), but at the time of report none of the patients had developed encephalopathy or recurrent bleeding esophageal varices. Splenorenal shunt is recommended as the elective procedure in cirrhosis if the splenic vein is of sufficiently large diameter.

6269 ^{131}I STUDIES OF THE LIVER AND PORTAL CIRCULATION. (E.) Rozenbilds, J. G. (Roy. Adelaide Hosp., Australia) and R. C. Bennett. Aust. New Zeal. J. Surg. 36(3): 234-237, 1967.

The hepatic uptake of rectally-admin. ^{131}I (20 μC) was studied in 36 subjects. A wide range of normal values was obtained in 20 normal controls; equilibration time (the time taken after inj. for activity to attain a steady level) ranged from 3-38 min., with a mean of 21.6 min. There was a considerable overlap between the range of values obtained in normal subjects and in patients with cirrhosis of the liver and hepatic tumors, but mean values for each group were almost identical; in 10 liver cirrhotics, equilibration time ranged from 4-38 min., with a mean of 20.6 min. In 1 case of portal hypertension studied before and after portacaval anastomosis, equilibration times were 13 and 11 min., resp. In 6 patients with hepatic tumor, equilibration time varied from 12-30 min., with a mean of 21.3 min. These results do not support the findings and conclusions of previous workers that this technic is valuable in the detection of hepatic abnormalities.

6370 EXPERIMENTAL STUDIES OF THE PATHOGENESIS OF SPLENOMEGALY IN THE PORTAL HYPERTENSION SYNDROME. (Fr.) Psomopulos, N. (U. Athens, Greece). J. Chir. (Paris) 93(1): 93-98, 1967.

Obstruction of the splenic vein produced a reduction in the flow of the splenic artery of dogs and an increase in spleen size, but after the obstruction was released the spleen returned to below normal size. In animals with splenic contraction induced by norepinephrine (0.02-0.04 mg/kg), blood circulation from the splenic artery to the splenic vein increased and a marked reduction of the difference between arteriovenous saturation levels was noted. Large arteriovenous anastomoses were seen in corrosion preparations of the spleen after norepinephrine admin.

6371 VASOPRESSOR RESPONSE TO THE INTRASPLENIC INJECTION OF NOREPINEPHRINE IN DOGS WITH AND WITHOUT PORTAL SYSTEMIC VENOUS COMMUNICATIONS. (E.) Aldrete, J. S. (Mayo Clin., Rochester, Minn.), C. Nava, D. C. McIlrath and G. A. Hallenbeck. Surgery 61(3): 461-465, 1967.

The femoral arterial pressor response to intrasplenic and peripheral venous inj. of norepinephrine was determined in normal dogs and in those with 1 of the following procedures: 1) portacaval transposition, 2) portacaval shunt, 3) ligated portal vein, and 4) constricted portal vein. A significant elevation of systemic blood pressure was noted in all dogs with portal collateral communications after the intrasplenic admin. of norepinephrine. Intrafemoral inj. of norepinephrine elevated the arterial pressure in all dogs, except those with portacaval transposition. These findings suggest that the systemic arterial pressor response to intrasplenic inj. of norepinephrine is an accurate method of determining the presence of portal-systemic communications in dogs.

6372 A ONE-STAGE HEPATECTOMY WITH VENA CAVAL HOMOTRANSPLANT. (E.) McBride, C. M. (U. Texas, Houston) and J. E. Healey, Jr. Surgery 61(3):455-460, 1967.

A one-stage hepatectomy, using a caudal vena caval homotransplant to bridge the defect, was performed on 10 adult mongrel dogs. This metho is rapid, requires a minimum of surgical dexterity and is not prone to technical failure The mean period of interruption of the portal and caval return flow was 6.5 min., with a range of 3-11 min. Change in mean blood pressure between the prehepatectomy reading and the 2-hr. posthepatectomy reading was -5 mm Hg, with a range from +10 to -15 mm Hg. Mean survival time was 16 hr.; 1 dog survived for 26 hr. At the end of 26 hr., the caudal vena cava homograft was grossly normal and only an infiltration of polymorphonuclear WBC and loss of muscle nuclei were seen microscopically. Over a 5-hr. follow-up period, the only significant changes detected were a fall in blood sugar (from a prehepatectomy mean of 114 mg% to less than 20 mg%, which required a mean time of 2 hr. after hepatectomy, with a range from 1-3 hr.) and an increase in serum uric acid, from approx. 1 mg/100 ml to approx. 8 mg/100 ml.

6373 CANNULATION OF THE THORACIC DUCT AND UMBILICAL VEIN IN PATIENTS WITH PORTA HYPERTENSION. (E.) Cueto, J. (West Virginia U. Med. Ctr., Morgantown) and R. A. Currie. Ann. Surg. 165(3):408-414, 1967.

The results of combined thoracic duct and umbilical vein cannulation in 5 patients (3 men 2 women; 33-71 yr. old) with portal hypertensio is described. Thoracic duct cannulation in the neck is a method for decompression of the portal venous bed in patients with portal hypertension due to intrahepatic blocks at the sinusoidal or postsinusoidal levels; it is accompanied by a significant decrease in portal venous pressure and can be used to control bleeding from esophageal varices. Preliminary observations indicate that this maneuver is valuable in the management of patients with this complication of portal hypertension. Umbilical vein cannulation also allows direct determination of portal venous pressure and visualization of the intrahepatic portal venous system. A combination of these 2 procedures is recommended in the diagnosis and management of selected patients with portal hypertension.

4 THE CANALICULAR CYST IN CHEMICAL HEP-
ATECTOMY. (E.) Becker, F. F. (550 First
., New York City), B. P. Lane and G. W. Teebor.
h. Path. (Chicago) 83(3):278-285, 1967.

noguanidine sulfate produced hepatic necrosis
n admin. to the chick embryo during the fourth-
th day of fertilization. A small segment of
liver parenchyma was spared this effect and
sented a tubular or multicystic appearance when
died by light microscopy. Using light and
ctron microscopy it was shown that these cystic
uctures were greatly dilated bile canaliculi
ch were lined by large numbers of embryonic
atocytes. No mitotic activity was demonstrated
any liver element until the end of the second
of fertilization, after which the normal liver
ucture was rapidly reconstituted. It is sug-
sted that the effect of aminoguanidine sulfate
on all liver cells is a prolonged mitotic in-
ition and that the canalicular cysts result
om failure of normal formation of the bile
inage system.

55 THROMBOSIS OF HEPATIC VEINS ACCOMPANYING
CARBON TETRACHLORIDE INDUCED CIRRHOSIS.
.) Reuber, M. D. (NCI, Bethesda, Md.) and E. L.
over. Arch. Path. (Chicago) 83(3):267-270, 1967.

ffalo strain inbred male and female rats (4 days,
wk., 12 wk., 24 wk. and 52 wk. old) were inj.
c. with CCl4 twice/wk. for 12 wk. Cirrhosis of
e liver and hepatic vein thrombosis developed.
rombosis occurred in older rats more frequently
an in younger rats, and it was also present in
les more often than females. The thrombosis
peared to be initiated by proliferation of
nous endothelial cells. It is suggested that
e proliferation resulted from toxic damage to
e venous endothelium by the CCl4.

56 AN ATTEMPT AT EVALUATION OF THE EFFECT
OF ACUTE ETHANOL INTOXICATION ON THE
IVER FUNCTION ON THE BASIS OF CERTAIN ENZYMATIC
ESTS. (Pol.) Łukasik, S. (3rd Clinic Intern.
is., Acad. Med., Wroclaw, Poland.), K. Wrabec,
. Hrynkiewicz and H. Szydlik. Pol. Tyg. Lek.
1(40):1519-1521, 1966.

e activity of 6 enzymes (SGOT, SGPT, phospho-
xose-isomerase, aldolase, alkaline phosphatase,
d gamma-glutamyl-transpeptidase) was slightly
gher in the serum of 27 patients with acute
hanol intoxication when compared with 90 healthy
bjects, but the difference was not statistically
gnificant. The difference was even less pro-
unced when a subgroup of nonalcoholics (15) and
coholics (12) was compared with the group of
althy subjects and a group of patients treated
r chronic alcoholism (110). The increase in mean
alues depends on a pronounced increase of this
ctivity in a small number of cases and not on
he increase of activity in the entire group,
as was shown by the evaluation of this material
by the elimination of individual results. These findings do not support the opinion that an increase in hepatic enzyme activity is caused by acute ethanol intoxication through its hepatotoxic action. The high enzyme activity in this group is due to a high frequency of hepatobiliary diseases; e.g. 6 previously had jaundice and 3 showed active inflammatory process in the liver or bile tract at the time of the study.

6457 THE EARLY STAGE OF LIVER INJURY IN THE ALCOHOLIC. (E.) Edmondson, H. A. (U. Southern California Sch. Med., Los Angeles), R. L. Peters, H. H. Frankel and S. Borowsky. Medicine (Balt.) 46(2):119-129, 1967.

Chronic alcoholic patients (100) without evidence of cirrhosis were studied at the time of an episode of acute alcoholism; 6 patients died, each of a different complication unrelated to alcoholic liver disease. The frequency of serum electrolyte deficiency was high and should be considered as a possible factor in sudden death. Liver biopsy specimens were obtained from 45 patients; microscopically, although fatty change was present in over 90%, there was a lack of severe hepatic alterations. More than 33% of the patients had swollen hydropic liver cells that were characterized by organelle disorganization when studied by electron microscope. Approx. 50% of the patients had some centrilobular intrasinusoidal collagen which appeared to originate in the spaces of Disse, but which could often be found in the intercellular spaces by electron microscopy.

6458 EFFECT OF ETHANOL ON RAT LIVER. III. LIPID COMPOSITION OF LIVER MITOCHONDRIA FROM RATS AFTER PROLONGED ALCOHOL CONSUMPTION. (E.) Lundquist, C. G. (St. Gorans's Hosp., Stockholm, Sweden), K. H. Kiessling and L. Pilstrom. Acta Chem. Scand. 20(10):2751-2754, 1966.

Long-term feeding of ethanol to rats influences liver lipid metabolism and the structure and function of the liver mitochondria. Mitochondrial lipids were quantitatively determined to see if the disturbed lipid metabolism changed the lipid composition of the liver mitochondria. There was a slight but nonsignificant decrease in the content of phospholipids and an increase in that of neutral lipids in mitochondria from alcohol-treated (ethanol, 15% (vol./vol.) soln. admin. over 8 mo.) rats (13), as compared with controls (10). Composition of the phospholipid fraction was almost identical in the 2 groups of animals.

6459 PROTEIN ANABOLISM AND FATTY LIVER OF THE ALCOHOLIC. (E.) Jabbari, M. (New Jersey Coll. Med., East Orange) and C. M. Leevy. Medicine (Balt.) 46(2):131-139, 1967.

Synthetic androgenic-anabolic steroids in large doses prevented ethanol-induced deposition of liver fat and facilitated its mobilization in Sprague-Dawley rats and man. Synthesis of nuclear RNA and repair of agranular reticulum which results from such therapy was associated with an increase in hepatic output of triglyceride. These results are interpreted as indicating damage of the agranular reticulum, reversible with appropriate therapy, as an important factor in the pathogenesis of fatty liver of the alcoholic. In spite of their potential toxicity, synthetic androgenic-anabolic steroids are useful adjuncts in the management of alcoholic patients with hepatic steatosis. Further studies are advocated to discover the mechanism for untoward effects of these drugs and modify their chemical structure so as to provide desired anabolism without untoward effects.

6460 PATHOCHEMICAL CHANGES IN AN EXPERIMENTAL HELIOTROPE-INDUCED LIVER DYSTROPHY. (Rus.) Abdullaev, N. K. (Uzbek Inst. Reg. Med. Tashkent, USSR). *Vop. Pitan.* 25(5):69-74, 1966.

Admin of heliotrine, (s.c.), an alkaloid obtained from *Heliotropium lasiocarpum* seeds, induced liver dystrophy in albino rats (180-200 g). The alkaloid was inj. daily during a period of 25 days (20, 15, and 10 mg per rat and day during the first week, the second week, and the remaining days, resp.). Some of the animals were harvested immediately after the last inj., some 20 days later. The metabolic changes induced by the alkaloid in the liver and in the serum of rats were characterized by biochemical methods. Livers of rats harvested immediately after the last inj. of heliotrine contained markedly less glycogen and β-lipoprotein, but more total lipids than those from healthy animals. Admin. of the alkaloid decreased also the autolipolytic and the esterolytic activity of the liver. On the other hand, the lipolytic activity of the fat tissue was increased in treated animals, leading to an increase of the level of nonesterified fatty acids in the serum. The β-lipoprotein content of the serum was higher in treated then in untreated animals. Thus the heliotrine-induced liver dystrophy leads to fatty infiltration of the liver. However, the accumulation of the fat is suppressed by increased excretion of the β-lipoproteins from the liver. The disease is accompanied also by inhibition of protein synthesis and markedly reduced respiration of the liver tissue. A similar pattern was observed also when rats were harvested 20 days after the last inj. of the alkaloid.

6461 EFFECT OF PREDNISOLONE AND OF METHANDROSTENOLONE ADMINISTRATION ON PATHOCHEMICAL SHIFTS IN EXPERIMENTAL HELIOTRINE HEPATITIS. (Rus.) Abdullaev, N. K. (Uzbek Inst. Reg. Med., Tashkent, USSR). *Probl. Endokr. Gormonoter.* 12(6):71-75, 1966.

The s.c. admin. of heliotrine, for a period of 25 days (20, 15, and 10 mg every second day to each rat during the first wk., the second wk., and the remaining days resp.), induced hepatiti
in white rats; it was manifested 20 days after the last inj. by decreased glycogen, protein, a
β-lipoprotein content, increased total lipid content, reduced autolipolytic activity and decreased respiration of the liver tissue. The changes were accompanied by increased lipolytic activity of the fatty tissue, and an increase in the levels of nonesterified fatty acids and β-lipoproteins in the serum, as well as by hypo
proteinemia. When rats poisoned by heliotrine were treated for 20 days after the last inj. of the alkaloid by p.o. admin. of 2 mg/100 g of prednisolone every second day, the pathologi
changes in fat and glycogen metabolism and in respiration of the liver tissue were essentiall
not reversed. However, changes in protein metabolism could be partially prevented by prednisolone treatment. Treatment with methandrostenolone under similar conditions was more effective. The glycogen protein, and β-lipoprotein content of the liver markedly improved. The protein content and the compositio
of the serum also became normalized. However, pathological changes induced by heliotrine in the total lipid content of liver, in the lipoly
activity of the fat tissue, and the β-lipoprote
content of the serum were not affected by treat
ment of rats with methandrostenolone.

6462 INFLUENCE OF ETHIONINE ON RIBOFLAVIN METABOLISM. (Rus.) Cherkes, L. A. (Inst. Nutr., Acad. Med. Sci., Moscow), S. A. Ganetskaia and S. G. Aptekar. *Vop. Onkol.* 12(9
55-59, 1966.

Wistar rats were inj. i.p. with D,L-ethionine (1 mg/g of wt.) and the level of riboflavin in their urine was determined 24 and 48 hr. after inj. The excretion of urinary riboflavin was markedly higher in ethionine-treated than in un
treated animals. On the other hand, the total riboflavin and flavin adenine-dinucleotide cont
of livers decreased sharply after admin. of ethionine. However, ethionine treatment did no
affect the sum of the free riboflavin and flavi
mononucleotide contents of rat liver. It is suggested that admin. of ethionine primarily decreased the level of liver ATP. As a consequ
the level of flavin adenine-dinucleotide in the liver was reduced.

6463 ANIMAL STUDIES ON THE SENSITIVITY TO TRYPSIN OF ISOLATED NORMAL AND INJURE
LIVER CELLS. (Ger.) Emmrich, R. (Karl Marx U.
Leipzig, Germany) and J. Fehres. *Acta Hepatosp*
(Stuttgart) 14(1):1-8, 1967.

Pieces of rabbit and rat liver (about 4 mm on each edge) were freed of blood by washing in phosphate and mg-free tyrode soln. The liver cells were mechanically separated; the cell suspension was centrifuged (400 rpm) and resuspended to yield a suspension of about 500,00
cells/ml. Trypsin was added to 1 ml of cell

sion so that the enzyme conc. varied in
ent preparation from 10^{-1}-10^{-10}%. After
. exposure of the cells to trypsin the
of cells intact in appearance were counted.
ver cells obtained from rabbits were of 4
ent groups: (a) Those from untreated
s; (b) Cells from rabbits sensitized by
ic inj. of human serum; (c) Liver cells
nimals poisoned with CCl_4; (d) Cells from
s poisoned with CCl_4 and sensitized to
serum. Liver cells from the rat were:
ver cells from normal rats; (2) Regenerated
cells after 70% resection of the liver,
after operation; (3) The same, 3 days
operation; (4) The same, 10 days after
ion; (5) Regenerated liver cells after 33%
ion of the organ, 3 days after operation;
lls from animals 3 days after 70% liver
ion (during the 3 days animals received
e chloride); (7) The same except the drug
was diethylstilbestrol dipropionate;
e same, except the drug (testosterone);
e same except the drug (prednisolone, solu-
in-H); (10) The same except the drug
cortone). The isolated liver cells with
damage showed a high breakdown rate but an
ged reactivity to trypsin by the intact
; sensitization to human serum did not
the rate of cellular breakdown on the
ivity to trypsin. After previous exposure
l_4 and sensitization to human serum,
ivity to trypsin was increased; however, the
down rate of the cells in suspension without
in remained normal. The liver cells on
hird day after 70% resection showed the
est natural reactivity to trypsin. Diethyl-
estrol dipropionate and prednisolone can-
d this increased sensitivity to trypsin. The
cal conc. of trypsin was between 10^{-4} and
g%; at the former conc. the cells were
ed; at the latter conc. all cells seemed
l.

NEGATIVE CORRELATION BETWEEN THE HEPATIC
CONCENTRATIONS OF ATP AND PORPHYRINS IN
AT INTOXICATED BY SEDORMID. (Fr.) Gajdos, A.
l Dieu, Paris), M. Gajdos-Torok, A. Palma-
s and L. Palma-Carlos. C. R. Soc. Biol.
s) 160(5):953-957, 1966.

ative correlation was found to exist between
ic levels of ATP and porphyrins. Four groups
ite female rats (about 200 g) were treated
llows: Group 1, normal controls; Group 2-4,
ls each received 400 mg/kg body wt. of
mid (allylisopropylacetylcarbamide)/day
days by gastric intubation. The animals
oup 2 were killed the day following the last
of Sedormid; the livers were immediately
ed and analyzed for ATP and porphyrins; those
oup 3 were kept for 2 days after the Sedormid
tment before being sacrificed, and the liver
zed in the same way; Group 4 remained for
ys after Sedormid prior to sacrifice and
sis. The av. values expressed as µM of
and as µg of free porphyrins/100 g of fresh
liver tissue were: Group 1 (controls), ATP 230; porphyrins 6.7; Group 2, ATP 150, porphyrins 73;. Group 3, ATP 185 porphyrins 28.0; Group 4, ATP 211, porphyrins 13.2. The comparison of the normal animals and those in Group 2 shows a significant negative correlation. In other animals, after the results reported above, the urinary excretion of δ-amino Levulinic acid, porphobilinogen, uro-and coproporphyrins was controlled without producing such wide differences in hepatic retention of porphyrins. Moreover, during the time when animals were under the influence of Sedormid and the hepatic conc. of porphyrins increased there was increased urinary excretion of porphyrins so that increased hepatic porphyrins did not result from decreased kidney excretion of these compounds.

6465 CLINICAL AND ANIMAL STUDIES ON THE LIVER TOLERANCE OF A SOPORIFIC COMPOUND. (Ger.) Clodi, P. H. (U. Vienna, Austria), H. Schnack and F. Wewalka. Wien. Med. Wschr. 49(116): 1072-1075, 1966.

The suitability of a nonbarbiturate sleeping compound (2-methyl-3-tolyl-4-oxybenzdiazine), Mozambin (M), with respect to its use by patients with liver disease was tested using the excretion of BSP as an index of liver function. The excretion of the dye av. 74% of the amount inj. in 90 min. in 16 normal rats; the av. for 8 rats after 350 mg Mozambin was 73%. Inj. of CCl_4 decreased BSP excretion; doses of 200 and 800 mg Mozambin did not significantly change the rate of dye excretion. The compound was admin. to patients with liver disease (200-400 mg/day p.o., or, 150 or 300 mg i.m.) for periods of 4-24 days; suppositories were also tried. The following determinations were made before and after treatment with Mozambin: (1) serum bilirubin level, (2) SGOT, and (3) leucine aminopeptidase. In almost all cases treated for more than 10 days with Mozambin, thymol turbidity, serum albumin and globulin were measured. Patients (15) were given the BSP test. The test groups comprised (1) cases with different internal diseases such as hypertension, bronchial asthma, spondylosis and illness after hepatitis, (2) cases with active liver diseases, (3) patients with compensated and decompensated liver cirrhosis, (4) patients with decompensated liver cirrhosis treated with Mozambin for longer periods of time and under the usual therapy for cirrhosis (vitamins and anabolic steroids), (5) cases with malignant tumors, (6) cases of acute hepatitis. Altogether 43 patients were tested. No effect of Mozambin was discovered upon the parameters studied nor on the RBC count. The mild hypnotic action of Mozambin can be used in treatment of patients with liver disease with favorable reactions. It should not be used when the patient is mentally disturbed.

6466 INFORMATION ON COMPARATIVE LEVELS OF HEPATIC ENZYMES, WITH PARTICULAR REFERENCE TO OCT AS AN INDEX OF THE HEPATOTOXICITY OF ANTIBIOTICS. (Fr.) Brette, R.

(Edouard-Herriot Hosp., Lyon, France), R. Truchot, J. F. Bolot and Y. Counitcansky-Cille. Rev. Int. Hepat. 16(7):1275-1291, 1966.

Liver function tests were performed before and after 6 days of antibiotic therapy in 88 patients. Spiramycin (3 g/day p.o.; 12 cases) had no effect on liver ornithine carbamyl transferase (OCT) levels; oleandomycin (3 g/day p.o.) and oxytetracycline (2.5 g/day p.o.) induced moderate increases in 1 of 8 and 1 of 10 cases, resp. A moderate increase in already elevated OCT levels was seen in 1 of 12 patients admin. penicillin G (2 million U/day i.m.). Significant increases in OCT activity were seen in 9 of 10 patients admin. erythromycin (3 g/day p.o.), 3 of 17 admin. tetracycline HCl (2.5 g/day p.o.), 2 of 9 admin. dihydrostreptomycin pantothenate (1.5 g/day i.m.), and 2 of 8 admin. colimycin (6 million U/day i.m.); these agents are known to be toxic to the liver, but no clinical signs of toxicity were noted. OCT proved much more sensitive than other liver function tests; none of the patients showed abnormal LDH, SGOT, SGPT, serum iron or bilirubin values.

6467 EXPERIMENTAL STUDIES ON THE HEPATIC EFFECTS OF TETRACYCLINE.

(E.) Miller, S. E. P. (West. Infirm., Glasgow, Scotland), R. N. M. MacSween, A. C. A. Glen, K. Tribedi and F. M. L. Moore. Brit. J. Exp. Path. 48(1):51-57, 1967.

Tetracycline was admin. by perfusion of the lateral tail vein to groups of 12 rats in doses of 100, 200 and 300 mg over a period of 30-40 min. followed by animal sacrifice 18 hr. later (Group 1) or similar groups were perfused for 24 hr. to total dosages of 30, 60, 120 and 140 mg and then either sacrificed at 6 hr. or 24 hr. (Groups 2 and 3 resp., half in each time period) after termination of tetracycline admin. In addition single i.m. inj. of tetracycline were admin. to 2 groups in doses of 100 and 200 mg, resp., and the rats were killed 18 hr. after inj. Control animals were admin. saline by similar routes and in corresponding doses. Histologic examination of rat parenchymal cells revealed a cytoplasmic vacuolation effect (either numerous and small or few and larger) concentrically arranged around the nucleus and observable throughout the lobule; pronounced fragmentation of the cytoplasm of mid-zone cells (confluent effect) and liver cell necrosis (focal to extensive). Employing fluorescent technics, tetracycline was demonstrated in the vacuoles of Group 2 rats but not in Group 3 rats. In single inj. studies, marked changes were produced even at the lowest dosages (100 mg/kg). Only 1 rat survived 18 hr. (liver showed confluent effect) and 9 rats died overnight (4 without liver cell changes) in the highest dose (300 mg/kg) group. Definite histological changes of the liver in the 24 hr. perfusion group were noted at 6 hr. with the smallest dose (30 mg/kg) and were time- and dose-dependent. Both SGPT and serum ornithine-carbamyl-transaminase activities increased after single inj. in dose-dependent fashion and thus indicated liver cell damage. SGPT significantly increase in all perfusion studies, except for 60 mg dose while no elevation of the serum ornithine-carba transaminase levels were noted after perfusion.

6468 CYTOPHOTOMETRIC AND CYTOCHEMICAL STUDIES ON THE EFFECT OF ACTINOMYCIN D AND THIOACETAMIDE ON RAT LIVER CELLS.

(E.) Vorbrodt, A. (Inst. Oncol., Gliwice, Poland), K. Vorbrodt, S. Krzyzowska-Gruca, Z. Stęplewski and M. Chorąży. Arch. Immun. Ther. Exp. 14(6): 818-824, 1966.

The effect of actinomycin D (100 μg/100 g body wt.) and thioacetamide (50 mg/kg body wt.) on regenerating and nonregenerating rat liver cells was studied using cytophotometry and cytochemical methods. Cytophotometric measurement showed that actinomycin D alone did not cause any distinct changes in the nucleoli, whil actinomycin D admin. together with thioacetamide abolished the effect of the latter. Nucleolar area was reduced from 12.3 μ^2 (thioacetamide-treated cells) to 6.2 μ^2 (thioacetamide and actinomycin D), as compared to the normal value of 4.5 μ^2. The RNA content expressed in arbitra U decreased from 3.54 to 1.09 (normal value is 1.13 U). These findings suggest that the maintenance of normal functional polarity of the parenchymatous rat liver cell is under nuclear control. Both actinomycin D and thioacetamide cause some as yet unknown disturbances in the distribution of guanosine triphosphatase A activity in nuclei and nucleoli of rat liver parenchymatous cells.

6469 EFFECTS OF BUTYLATED HYDROXYTOLUENE ON THE ULTRASTRUCTURE OF RAT HEPATOCY

(E.) Lane, B. P. (New York U. Sch. Med., N. Y.) and C. S. Lieber. Lab. Invest. 16(3):342-348, 1967.

Sprague-Dawley rats (36) were pair-fed nutritio ally adequate liquid diets with or without butylated hydroxytoluene (1.7 mg/calorie on the first day, 2.2 mg/calorie on the second day, and 2.8 mg/calorie thereafter) over periods ranging from 1-24 days. An additional 18 rats received butylated hydroxytoluene, 1.4 g/kg body wt., in a single dose admin. via gastric tube and were then fed a control liquid diet. Liver specimens were obtained for examination by electron microscopy at 1, 2, 3, 6, 7 and 24 days after onset of ingestion of the agent in food; groups of 3 animals from those receiving a singl dose by gastric tube were sacrificed at 16, 24 and 48 hr. and liver specimens were similarly examined. All specimens from rats receiving butylated hydroxytoluene either in their diet or by a gastric tube exhibited a proliferation of smooth-surfaced endoplasmic reticulum within some hepatocytes. The proliferation of smooth endoplasmic reticulum was noted in 20-50% of liver cells in rats sacrificed after 1 and 2

of ingestion of the drug, in 70-80% of the
r cells in rats receiving the drug for 3-7
and in more than 50% of the hepatocytes
pecimens from animals receiving the drug
24 days. From 20-50% of the cells in
imens from rats sacrificed 1-2 days after a
le dose showed the change; and at 16 hr.,
tered cells ranging up to 15% of those ex-
ed showed proliferation of granular endo-
mic reticulum. All liver specimens obtained
ng the first 3 days of continuous drug in-
ion or in the 2 days after admin. of a single
e dose by gastric tube exhibited an increase
eterochromatin aggregated about the nucleus,
compared to control samples from untreated
er mates. Increased mitotic activity also
seen in two-thirds of the samples after 1-4
of continuous ingestion of butylated hydroxy-
ene. No period of peak activity was noted.
ncrease in mitotic activity was seen in rats
n a single dose of the agent by gastric tube.
effects of butylated hydroxytoluene differed
those of other drugs in that its repeated
n. resulted in both increases in hepatocytic
nular endoplasmic reticulum and in enhanced
tic activity.

IRON-LOADING, FIBROSIS, AND HEPATIC
CARCINOGENESIS. (E.) Dunn, W. L. (U.
ish Columbia, Vancouver, Canada). Arch. Path.
cago) 83(3):258-266, 1967.

subjected to massive doses of parenteral Fe
ran, or to splenectomy, as a means of producing
tic siderosis, did not show obvious enhance-
of the cirrhosis, or alteration in the rate
ppearance or final incidence of hepatomas
fed a diet containing DL-ethionine for
ods up to 10 mo. Both massive overloading
splenectomy resulted in increased Fe storage
rabeculae, Kupffer cells, liver lobules and
nerative nodules, being more pronounced in
former. Isolated atypical liver cells were
n noted in "survival zones" about early foci
ecrosis. Their possible relationship to
later regenerative nodules, to eventual
tocarcinoma and to the residual cirrhosis is
cussed.

ROLE OF INTESTINAL MICROORGANISMS IN
DETERMINING CYCASIN TOXICITY. (E.)
z, M. (NIH Bethesda, Md.), D. W. E. Smith,
. McDaniel and G. L. Laqueur. Proc. Soc. Exp.
. Med. 124(3):691-697, 1967.

role of intestinal bacteria in converting the
rally occurring glucoside cycasin to its
inogenic and hepatotoxic aglycone (methyl-
ymethanol) was studied. Germfree male
ague-Dawley rats, in which cycasin is nontoxic,
monocontaminated with Streptococcus fecalis,
obacillus salivarius salicinius or L. salivar-
salivarius before intragastric admin. of cyca-
(750 mg/kg body wt., which is considerably
er than the LD_{50} for this strain of rats).
Levels of glucosidase activity in the bacteria were determined by assay of cell-free extracts, using cycasin as a substrate. The toxicity of cycasin in rats given the various bacteria and the amounts of unchanged cycasin excreted were consistent with the glucosidase assays. Monocontamination of germfree rats with S. fecalis resulted in a striking reduction in cycasin excretion, and microscopic examination of livers of these rats showed severe centrilobular hemorrhagic necrosis. A definite but less impressive reduction in cycasin excretion occurred in rats monocontaminated with L. salivarius salicinius; liver sections of these animals showed mild evidence of injury consisting chiefly of loss of cytoplasmic basophilia and occasional necrotic parenchymal and Kupffer cells. Rats monocontaminated with S. fecalis which received cycasin on the fifth day after inoculation excreted more than twice as much cycasin as those monocontaminated for 7 days; this illustrates the importance of allowing sufficient time for intestinal colonization of germfree rats by a monocontaminant. It is concluded that intestinal microorganisms deglucosylate cycasin to yield the toxic aglycone, and that variations in the intestinal flora probably play a role in determining the toxicity of ingested cycasin.

6472 LYMPHATIC CAPILLARIES OF THE LIVER IN CONDITIONS OF RADIATION AND SURGICAL INJURY IN EXPERIMENTAL CONDITIONS. (Rus.) Ogii, P. E. (Ternopol Med. Inst., USSR). Klin. Khir. (Kiev) (3):28-33, 1967.

6473 NUCLEAR FATTY ACIDS IN LIVER OF RATS SUBJECTED TO WHOLE-BODY IRRADIATION. (It.) Slaviero, G. E. (U. Pavia, Italy), E. Bobbio Pallavicini and A. Zanetti. Minerva Radiol. 12(3):90-94, 1967.

6 PRELIMINARY RESULTS OF STUDIES ON THE
APPLICATION OF THE INTRADERMAL TEST
H GAMMA GLOBULIN IN VIRUS HEPATITIS. (Pol.)
uness, W. (2nd Surg. Clin. Lublin, Poland),
Bierut, T. Franczak, H. Gawronowa, C. Horoch,
Kornas, I. Mierzejewska, E. Szymanek, Z.
ski and H. Zochowska. Pol. Tyg. Lek. 21(44):
9-1682, 1966.

radermal test with 15% human gamma globulin
admin. to 998 persons (452 males, 546 females;
up to 14 yr., 520 of 998; 15-more than 50 yr.,
of 998), of whom 669 received at the same time
ontrol test (20% human albumin). Erythema and
iltration 10 or more mm in diameter were
sidered to be a positive reaction. In 13 of
patients with viral hepatitis the positive
aneous reaction was confirmed equally with
gamma globulin and the control and thus were
evaluated. Control tests were negative in
of the cases. Of 299 patients with viral
atitis 66.3% had a positive test. In the
ients with suspected oral and parenteral routes
infection the intradermal test was positive
m the first day of the disease. The highest
centage of positive tests was found in persons
er than 50 yr. (78%) and the lowest in children
to 6 yr. of age (53%). On the seventh day of
ease 47.8% of the cases showed positive results
after 21 days only 35.2%. Of 52 cases with
evere course of the disease 71% had a positive
ction; of 148 with a moderately severe course
5% had positive reactions; and of 91 mild
es 60.0% had positive reactions. Of 207
sons in contact with viral hepatitis patients
2% had positive reactions, which was also
nd in 6.4% of 264 healthy persons. Of 121
sons with other diseases 12.4% had positive
ctions as well as 31% of 94 persons with other
eases of the liver and biliary tract.

7 COMPARISON BETWEEN THE BEHAVIOUR OF
VARIOUS SERUM ENZYME ACTIVITIES (GUANASE
TRANSAMINASE) AND HOYT-MORRISON TEST IN
AN VIRAL HEPATITIS. (It.) Monti, G. (U.
ua, Italy), S. Pepi, P. Mazzucato and A.
liamonte. Policlinico [Prat.] 73(47):1577-
0, 1966.

values of serum guanase (Hue-Free method)
transaminase (Tonhazy method) activity and
se obtained by the Hoyt-Morrison test were
pared in 135 patients with viral hepatitis
racterized by jaundice. Positive serum
nase activity, transaminase activity, and
t-Morrison tests were observed in 93.1%,
1%, and 48.27%, resp., of 29 patients in
m jaundice appeared during days 1-10 of the
ease; 70.37%, 88.88%, and 58.14%, resp., of
patients (days 11-20); 50%, 62.5%, and 62.5%,
p., of 24 patients (days 21-30); 34.37%,
89%, and 75.86%, resp., of 29 patients (days
40); 26.92%, 30.77%, and 73.07%, resp., of
patients (days 41-50). Results indicate a marked increase in enzyme activity during the more acute periods of the disease with a gradual decrease thereafter. The decrease was more rapid in serum guanase levels, suggesting that this enzyme is a specific indicator of hepatic necrosis. On the other hand, the Hoyt-Morrison test became positive during the later phases, and the persistence of a positive reaction may be an indication of chronic progression of the disease.

6488 USE OF IMMUNOFLUORESCENCE METHOD FOR DETECTION OF ANTIGEN IN LIVER CELLS OF PATIENTS WITH INFECTIOUS HEPATITIS. (Rus.) Ketiladze, E. S. (Ivanovskii Inst. Virology, Acad. Med. Sci., Moscow), E. A. Paktoris, I. V. Shakhgildian and N. N. Zhilina. Vop. Virus. 11(6):675-680, 1966.

Liver cells were collected by punch biopsy from 30 children with infectious hepatitis and were examined by the indirect fluorescent antibody method for the presence of a specific viral antigen. Liver cells collected from 15 adults with hepatitis of nonviral etiology served as control. Convalescent sera and human gamma globulin were used for detection of viral antigen. Rabbit gamma globulin containing antibodies against adenoviruses was used in control stainings. Specific antigen could be detected by both convalescent sera and human gamma globulin in livers of 9 of 15 patients with an acute form of infectious hepatitis accompanied by swelling of the liver, jaundice, and increase in the level of blood transaminases. Positive stainings were much more frequent during the early (seventh-fifteenth day after the appearance of the symptoms) than later stages of the disease. Similarly, with increasing severity of the disease the probability of the occurrence of positive staining increased. Specific fluorescence was seen exclusively in the cytoplasm. The nuclear localization of fluorescence observed with one of the samples after staining with control and anti-adenovirus rabbit gamma globulin was shown to be due to additional adenovirus infection. Specific antigens could not be demonstrated in liver cells collected from children with a chronic form of disease or from adults with nonviral hepatitis after treatment with convalescent sera or human gamma globulin.

6489 INVESTIGATION OF VIRUSES ISOLATED FROM PATIENTS WITH BOTKIN'S DISEASE AND THEIR CONTACTS. (Rus.) Nuromskaia, O. A. (Med. Inst., Lugansk, USSR). Vop. Virus. 11(6):721-724, 1966.

Blood samples (148), 192 samples of feces, and 195 samples of nasopharyngeal washings, collected from patients with epidemic hepatitis and from their contacts, were examined for the presence of specific complement fixing antibodies. Cultures of D-6 cells were inoculated with positive samples. The nasopharyngeal washings and blood samples were heated at 56°C for 30 min. before inoculations. Of 57 cytopathic agents isolated and carried through 7 subsequent passages, 9 were derived from nasopharyngeal washings, 19 from feces and 29 from the blood. The titers of the isolated agents (extra-plus intracellular) were $10^{2.5}$-$10^{3.5}$, $10^{1.0}$-$10^{1.5}$, and 10^{0}-$10^{0.5}$ TCID$_{50}$ (tissue culture inhibitory dose) per 0.1 ml in D-6, HEp-2, and HeLa cell cultures, resp. The level of intracellular virus was much higher than that of extracellular. The agents were not inactivated by heating at 56°C for 30 min., were not sensitive to treatment by ether, agglutinated rat RBC in low dilutions, and did not multiply in embryonated eggs. They were not neutralized by anti-Coxsackie B (types 1-6), anti-ECHO (types 1-29), and anti-polio (types I-III) sera. Convalescent sera collected from patients who had infectious hepatitis neutralized these agents in dilutions up to 1.8-1.16. All agents isolated showed positive complement fixation reaction with anti-adenovirus sera. This fact indicated that the agents may be antigenically related to adenoviruses.

6490 THE COURSE OF DIABETES MELLITUS IN EPIDEMIC HEPATITIS.

(Rus.) Moskovich, E. G. (Botkin City Clin. Hosp., Moscow) and K. L. Tregubova. Probl. Endokr. Gormonoter. 12(6):40-43, 1966.

The course of diabetes mellitus was studied in 50 patients with infectious hepatitis (Botkin's disease). Forty patients already had diabetes before the appearance of hepatitis symptoms, while in 10 of them diabetes developed after these symptoms appeared. In the latter group of patients a latent form of diabetes was apparently activated by the hepatitis or in individuals with affected insular apparatus, possibly by glucocorticoids used for treatment of hepatitis. None of the forms of diabetes mellitus developed during hepatitis were resistant to insulin. As a rule, infectious hepatitis increased the severity of diabetes mellitus, necessitating treatment with increased doses of insulin or use of insulin in patients who were not treated with it before hepatitis. It is concluded that diabetes mellitus is not a contraindication for glucocorticoid treatment in infectious hepatitis.

6491 DIAGNOSTIC AND PHYSIOPATHOLOGICAL SIGNIFICANCE OF CHANGES IN SERUM POLYPEPTIDASE ACTIVITY IN CHRONIC HEPATITIS.

(Rum.) Dragomirescu, M. (Contagious Dis. Clin., Inst. Med., Timisoara, Rumania) and L. Dragomirescu. Med. Intern. (Bucur.) 18(10):1173-1178, 1966.

Serum polypeptidase changes in patients with epidemic hepatitis and obstructive jaundice (lithiasis) were investigated by titrimetric and colorimetric methods (451 determinations). The latter technic was found to be far superior (diagnostic index = 92.4%, as against 76% for the titrimetric method). Also, the values obtained with the colorimetric method paralleled those
obtained in determinations of serum proteolyt
enzymes and SGPT titers in viral hepatitis.
is concluded that while the diagnostic and
prognostic value of the colorimetric method
superior, both methods reflect the progressic
of hepatic lesions.

6492 STUDY OF THE METABOLISM OF TRYPTOPH IN DIFFERENT HEPATO-DIGESTIVE DISEA I. VIRAL HEPATITIS.

(Fr.) Lemonnier, F. (S
Antoine Hosp., Paris), C. Charpentier, B.
Chevrel, A. Lemonnier and J. Caroli. Rev. Fr
Etud. Clin. Biol. 12(1):71-77, 1967.

Tryptophan metabolism (5 g p.o.) was studied
38 occasions in 16 patients in various stages
viral hepatitis. In 12 tests, significant
abnormalities were seen: increased kynurenin
and acetylkynurenin excretion (11), increased
excretion of free or conjugated hydroxykynure
anthranilic acid or kynurenic acid (7 each),
and increased hydroxyanthranilic acid (1 test
but xanthurenic acid was normal on 11 of 12
occasions. In 10 tests the excretion pattern
were similar but changes were less marked
(described as "subnormal" excretion tests);
the other 16 were normal. During the first
after the onset of jaundice, when the SGOT ar
SGPT levels were elevated (usually markedly)
3 of 11 tryptophan loading tests were normal
were abnormal and 2 were subnormal. After 3
of evolution, when the transaminases were st
elevated, 3 of 10 tests were abnormal, 3 were
subnormal and the others were normal. After
about 30 days, only 1 of 10 tryptophan tests
was abnormal (the others were normal or subn
in these patients the transaminases were sti
elevated but beginning to decrease. The tryp
phan loading test did not afford a direct mea
ment of liver cell damage. The principal me
bolic anomaly in the acute stages of infecti
hepatitis seemed to be in the transformation
kynurenin into hydroxykynurenin.

6493 INVESTIGATIONS ON URINARY EXCRETIO ACID MUCOPOLYSACCHARIDES IN THE CO OF VIRAL HEPATITIS AND THEIR CLINICAL SIGNIF

(Pol.) Stempień, R. (Infect. Dis. Clin., Lo
Poland), E. Schmidt and L. Tomaszewska. Pol
Tyg. Lek. 21(44):1686-1689, 1966.

Daily urinary excretion of acid mucopolysacc
studied on 111 patients (mostly males; age 2
yr.) showed (in 50 patients with viral hepat
without coexisting diseases) an av. value of
7.90 mg% (expressed as glucuronic acid), as
compared to 40 controls (age 20-70 yr.) with
6.25 mg%. In 32 patients with prolonged hep
tis, after viral hepatitis, and liver cirrho
the acid mucopolysaccharide excretion was in
creased showing an av. value of 21.0 mg%/day
In 15 patients with viral hepatitis and pulm
tuberculosis the av. daily excretion was 16.
and in 12 patients with viral hepatitis and
diabetes the value was 17.1 mg%. In half th

nts with viral hepatitis and rheumatic
se the av. daily excretion was 18 mg% and
hers 93 mg%.

BLOOD FRUCTOSE AND INORGANIC PHOSPHORUS
AFTER ORAL SUCROSE LOAD AS AN INDEX OF
OSE METABOLISM. DISTURBANCES OF FRUCTOSE
OLISM IN PATIENTS AFTER VIRAL HEPATITIS.
) Poznańska, H. (2nd Infect. Dis. Clin.,
w). Pol. Tyg. Lek. 21(40):1521-1524, 1966.

ose curves after oral loading with sucrose
determined in 20 of 51 patients with a history
ral hepatitis 2-3 yr. earlier. At the time
lease 8 of 20 showed normal fructose curves,
20 had varying curves and 4 of 20 pathologic
s. One patient was released during hormonal
py with a probable influence on the normal
e of the fructose curve in spite of symptoms
ffuse hepatic inflammation; however, a check-
owed a pathologic fructose curve. At
up the fructose curve was normal in 7 of 8
of 7, resp., pathologic in 1 of 8 and 3 of 4,
, and varying in 1 of 4. Besides these, 14
nts were examined who had viral hepatitis
mo. earlier and fructose curve was not
mined during hospitalization. Four showed
l fructose curves and no additional or
cal changes were evident; 7 showed varying
s, of whom 5 had slight hypoalbuminemia
6%), 1 slightly increased thymol test; 3
d pathologic curves. Therefore normal
ose curves upon discharge remained normal,
ng curves became normal, and pathologic curves
ned so in some patients. Pathologic curves
usually accompanied by slight abnormalities
rtain functional liver tests. Therefore the
fructose curve after oral loading with
se is a very sensitive index of functional
rbances of the liver cell.

THE EFFECT OF PREDNISONE ON VENOUS
PRESSURE IN VIRAL HEPATITIS. (Pol.)
ński, B. (1st Intern. Dis. Sch., Warsaw).
Tyg. Lek. 21(44):1696-1697, 1966.

s pressure was measured in 23 patients with
hepatitis, of whom 21 were treated with
rate doses of cortisone (30-50 mg/day) and
high doses (100-200 mg/day). Measurements
made before treatment with cortisone at 48
44 hr. of treatment, at the third day reduc-
of dose, at discontinuation of treatment and
scharge. It was found that cortisone norma-
venous pressure in the patients with viral
titis. A normalization of the serum protein
tion was observed also, when compared to the
nts not treated by cortisone. One of 2
nts treated by large doses of cortisone died
autopsy revealed renal tumor with metastases
ungs and brain.

CHRONIC ACTIVE HEPATITIS TREATED WITH
6-MERCAPTOPURINE. SUSTAINED REMISSION.
(E.) Geenen, J. E.(Racine Med. Clin., Wis.),
G. T. Hensley and D. H. Winship. Ann. Intern.
Med. 65(6):1277-1283, 1966.

The histological, biochemical and clinical aspects of chronic active hepatitis in a 21-yr.-old Caucasian housewife were observed over a 3-yr. period; her response to glucocorticoids and 6-mercaptopurine was documented with serial liver function tests and liver biopsies. On 2 occasions, the patient was given p.o. prednisone (first, 60 mg/day, tapered over an 8-mo. period to 10 mg/day; second, 30 mg every other day, increased to 30 mg/day, and then gradually decreased over 4 mo. to 15 mg/day), but relapsed after its withdrawal. The patient was then given 6-mercaptopurine (200 mg/day, gradually decreased over a 3.5-mo. period to 100 mg/day), which was discontinued 10.5 mo. after its initiation because of pregnancy. This invoked a sustained remission after 2 yr. of active hepatic disease, and 6 mo. after cessation of therapy the disease had not relapsed. This is the first reported case of well-documented chronic active hepatitis in which remission lasted longer than 6 mo. after termination of purine analog therapy.

6497 POSTSPLENECTOMY VIRAL HEPATITIS. (E.)
Stone, H. H. (Emory U. Sch. Med.,
Atlanta, Ga.), D. G. Stanley and R. H. DeJarnette.
J.A.M.A. 199(11):851-853, 1967.

During an 18-yr. period, 382 patients underwent splenectomy for various indications (with a mortality rate of 21.5%), 8 of 82 deaths after splenectomy were definitely attributed to a fulminant form of viral hepatitis, which usually occurred between the fourth and tenth wk. after operation. There were only 2 survivors out of 10 in whom viral hepatitis developed within a 6-mo. period after splenectomy (80%) mortality). Of 434 total cases of infectious hepatitis during the 18 yr. period, there were 30 deaths (6.9%) mortality). For serum hepatitis mortality was 21.4% (27 deaths) in a series of 126 patients; 8 of the 27 deaths occurred in patients who had undergone splenectomy within the 6-mo. period before onset of hepatitis. The incubation period in 5 of these 8 patients was lass than 6 wk. and could therefore represent the transfusion of infectious hepatitis virus rather than serum hepatitis virus in the admin. blood. In an experimental study of viral hepatitis in weanling (18-22 day old) mice, mortality was increased 2.5 times by performance of splenectomy before virus inoculation. It is postulated that the spleen does serve in some type of protective capacity against the hepatitis virus.

6498 VIRAL HEPATITIS IN NARCOTICS USERS.
AN OUTBREAK IN RHODE ISLAND. (E.)
Rosenstein, B. J. (601 N. Broadway, Baltimore,
Md.). J.A.M.A. 199(10):698-700, 1967.

An outbreak of viral hepatitis occurred among narcotics users in Rhode Island during the autumn of 1964 and winter of 1965. A history of i.v. drug use was elicited from 27 persons, 1 of whom had 3 distinct episodes of hepatitis; 24 of 27 were males, 17-30 yr. old, and they accounted for 30% of all reported cases of hepatitis in this age group. The majority of patients were hospitalized, but they had a mild course and there were no deaths. Eleven of 27 (41%) were not recognized initially as drug users by their attending physicians. Epidemiologic data suggested that the cause of the outbreak was the virus of serum hepatitis, and that it was transmitted by the use of contaminated inj. equipment.

6499 STUDIES ON THE TRANSMISSION OF HUMAN VIRAL HEPATITIS TO MARMOSET MONKEYS. I. TRANSMISSION OF DISEASE, SERIAL PASSAGES, AND DESCRIPTION OF LIVER LESIONS. (E.) Deinhardt, F. (Presbyterian-St. Luke's Hosp., Chicago), A. W. Holmes, R. B. Capps and H. Popper. J. Exp. Med. 125(4):673-699, 1967.

Inoculation of human sera or plasma obtained during the early phase of viral hepatitis induced chemical and morphological hepatic disease in marmosets in 2 of 5 experimental series. The disease was transmissible in series from marmoset to marmoset with an apparent increased virulence of the causative agent in later marmoset passages. Chemical evidence for the disease was elevation of the activity of SGOT and serum isocitrate dehydrogenase and of serum bilirubin. In serial liver biopsy specimens interpreted under code, a form of hepatitis, exhibiting some of the characteristics of human viral hepatitis, was readily distinguishable from nonspecific changes. The morphological changes preceded the biochemical alterations and persisted after them. These results suggest that marmosets may be susceptible to human hepatitis; if these observations are corroborated, marmosets may provide good experimental models for this disease. Final and definitive evidence that the hepatitis observed in marmosets is caused by agents of human viral hepatitis is still lacking.

6500 VIRAL HEPATITIS AMONG AMERICAN MISSIONARIES ABROAD. A PRELIMINARY STUDY. (E.) Cline, A. L., J. W. Mosley (1600 Clifton Rd., Atlanta, Ga.) and F. G. Scovel. J.A.M.A. 199(8):551-553, 1967.

The occurrence of icteric viral hepatitis among 558 American missionaries (representing 175 households) who had lived an av. of 5.7 yr. in 49 countries in Latin America, Africa and Asia between 1945-1964 and who did not receive immune globulin prophylaxis was studied retrospectively. The attack rate for all ages was 1.6%/yr.; it increased progressively from 0.6%/yr. among children under age 10 to a peak of 4.0%/yr. among those in the 20-29 yr. old group. It then decreased among older adults, but still remained higher than the level among children. There were no differences in age-specific attack rates between men and women. These findings indicate that viral hepatitis is a significant health problem among American missionaries. The pattern in relation to duration of residence abroad suggests that in order to have reduced the incidence of viral hepatitis, the admin. of immune globulin would have been required throug out the period of residence abroad.

6501 SERUM HEPATITIS AMONG SWEDISH TRACK FINDERS. AN EPIDEMIOLOGIC STUDY. (E. Ringertz, O. (Nat. Bact. Lab., Stockholm) and B. Zetterberg. New Eng. J. Med. 276(10):540-546, 1967.

During 1957-1963, 568 cases of serum hepatitis occurred among cross-country track finders (runners) in Sweden, showing an increasing numbe of cases each yr. The disease began in the west parts of Sweden and slowly spread over the whole country. The incubation period of the disease was estimated to be 90-150 days. More than 95% of the track finders received wounds or scratche during the competitions. Transmission of the disease most probably occurred by inoculation of the virus into these lesions, mainly at washi after conclusion of the competitions. The epide was terminated when, among other regulations, adequate clothing was made compulsory. During 1965-1966 another outbreak, including 42 cases, occurred shortly after these regulations had been suspended.

6502 VIRAL HEPATITIS IN A GROUP OF BOSTON HOSPITALS. III. IMPORTANCE OF EXPOS TO SHELLFISH IN A NONEPIDEMIC PERIOD. (E.) Koff, R. S. (Massachusetts Gen. Hosp., Boston), G. F. Grady, T. C. Chalmers, J. W. Mosley and B. L. Swartz. New Eng. J. Med. 276(13):703-710 1967.

During a nonepidemic period, 270 adult patients with viral hepatitis and an equal number of matched controls were studied by means of identi epidemiologic interviews designed to determine the frequency of easily recognizable and less apparent sources of transmission. Fifteen patients who admitted to narcotic addiction and 70 patients with hepatitis after transfusion had no other potential exposures more frequentl than their respective controls. In the remaini 185 the obviously important exposure to jaundice persons or patients known to have hepatitis occurred frequently; however, several less obvi potential exposures occurred so frequently in patients with hepatitis, in comparison to contr that these were thought to be significant source of nonepidemic hepatitis. These included ingestion of raw clams and oysters, contact with acutely ill but nonjaundiced children, tissue penetration by physicians and out-of-state travel. The ingestion of steamed clams was significantly more frequent in the hepatitis group, thereby suggesting a causal association between hepatitis and ingestion of cooked shellfish; ingestion of steamed clams and raw

lfish appeared to be as common a source of
ction as contact with jaundiced individuals.
ents with hepatitis admitting to narcotic
tion and those with posttransfusion viral
titis generally had an afebrile, insidious
t of illness, with infrequent preicteric,
romal symptoms. However, nontransfused,
ddict patients more frequently had abrupt
ts of illness, with fever and prodromal
toms. These clinical features were not
ific enough to identify the mode of transmis-
in the individual patient.

CHIMPANZEE-ASSOCIATED HEPATITIS. AN OUTBREAK IN OKLAHOMA. (E.) Mosley, J. W.
0 Clifton Rd., Atlanta, Ga.), H. P. Reinhardt
F. R. Hassler. J.A.M.A. 199(10):695-697, 1967.

of six persons who were in continuous physical
act with two chimpanzees developed infectious
titis. The only individual who did not
me ill had a history of a childhood disease
nosed as infectious hepatitis. The two
panzees were sent to the University of
homa 54 days and 19 days after their arrival
he United States. The animals possessed no
toms of an illness recognizable as infectious
titis. The outbreak of the disease occurred
ays after their arrival at the university.
5 cases had their onsets within a 2-3-wk.
od, suggesting a common exposure. No other
s were reported in the surrounding country
among persons handling the chimpanzees prior
hipment. Close examination failed to disclose
outside origin of the disease. Food was
lied from a common source and was also served
eople who did not contract the disease.
form organisms were not recovered from water
les. Fluorescein tests on the toilet facilities
in the animal house were negative. The pres-
evidence is considered sufficient to justify
designation of infectious hepatitis as a
mpanzee-associated" disease.

METABOLISM OF I^{131}-LABELLED THYROXINE
AND TRIIODOTHYRONINE IN LIVER CIRRHOSIS.
thman, S. M. (Amer. U., Beirut, Lebanon)
A. Haydar. J. Med. Liban. 19(5):201-212,

function studies were done on 9 patients
rrhosis of the liver; in 5, low protein-
odine and elevated triiodothyronine RBC
were found. There was no correlation
thyroid function and any of the liver
n tests. The metabolism of ^{131}I-labeled
ne and triiodothyronine was studied in 6
tients. The turnover rate of thyroxine
longed in 2 patients with liver cirrhosis,
t of triiodothyronine gave variable results
ould not be correlated with any of the
unction tests.

DETERMINATION OF FREE THYROXINE IN SERUM
OF PATIENTS WITH CIRRHOSIS OF THE LIVER.
ollander, D. (U. Kansas Med. Ctr., Kansas
J. C. Meek and R. T. Manning. New Eng. J.
5(16):900-902, 1967.

of patients with liver cirrhosis in whom
d thyroid-function tests were abnormally
compared with a similar group of patients
rmal protein-bound iodine and uptake of
the thyroid gland. The latter group had
l percentage of free thyroxine as well as
ree thyroxine iodine conc. In contrast,
s with low protein-bound iodine and ^{131}I
had an elevation in the percentage of free
hyroxine that resulted in a normal total
yroxine iodine conc. Serum free thyroxine
able in clarifying the metabolic status of
ic patients; in spite of a low protein-
odine and ^{131}I uptake, the patients de-
were euthyroid.

ERYTHROCYTE REDUCED GLUTATHIONE LEVELS
IN HEPATIC CIRRHOSIS. (It.) Crosti,
J. Milan, Italy), G. Sirchia, S. Ferrone
M. Sironi. Riforma Med. 80(40):1098-1105,

nations of RBC levels of reduced glutathione
r method), of reduced glutathione stability
-'s acetylphenylhydrazine method), and of
els of glucose-6-phosphate dehydrogenase
rg-Horecker method) were conducted in 56
s (48 men and 8 women; age 34-69 yr.) with
is of the liver. Reduced glutathione levels
ss than normal in 19 patients; stability
s than normal in 21; phosphate dehydrogenase
were greater than normal in 14. The values
d were then compared by electronic calculator
other clinical and hematochemical parameters
r to obtain a comprehensive picture of
ients' clinical condition. Of significance
finding that reduced glutathione levels
oility were inversely proportional to serum free bilirubin levels and that phosphate dehydrogenase activity was inversely porportional to the number of RBC and to SGPT levels. The former relationship may indicate an interaction with the extensive hemolysis almost always observed in these patients.

6565 RESPECTIVE VARIATIONS IN SIDEREMIA AND SIDERURIA IN CIRRHOTICS AND ALCOHOLICS AFTER THE DESFERRIOXAMINE TEST. (Fr.) Aron, E. (Fac. Med. Pharm., Tours, France), J. D. Weill, A. Galand and M. Domenech. Arch. Franc. Mal. Appar. Dig. 55(12):1159-1166, 1966.

Desferrioxamine B methanesulfonate (Desferal; 2 inj. of 500 mg i.m., usually at a 6-hr. interval) induced no significant changes in serum or urinary Fe levels in 8 control subjects (av. before treatment 112.5 μg/100 ml and 1.382 μg/24 hr., resp.; after treatment 123.2 and 1.854 μg, resp.). In 20 patients with cirrhosis, serum and urinary Fe levels were significantly elevated (139.5 and 1.537 μg, resp.); the desferrioxamine test induced a slight but significant increase in sideruria (av. 3.823 μg/24 hr.), but did not affect serum Fe levels (av. 133.5 μg/100 ml). There was no apparent correlation between the severity of the disease and the degree of sideremia. In 8 alcoholics without clinical or biochemical signs of cirrhosis, av. urinary iron levels increased (1.288 to 2.266 μg/24 hr.) after the desferrioxamine test, while serum levels remained unchanged. This difference in iron excretion was significant, but less marked than in the cirrhotic patients. Liver biopsy studies following desferrioxamine admin. showed significant hepatosiderosis in the cirrhotic patients and less massive accumulation in the alcoholic patients.

6566 SECRETION OF PANCREATIC ENZYMES. III. RESPONSE OF PATIENTS WITH CIRRHOSIS TO SECRETIN AND PANCREOZYMIN. (E.) Zieve, L. (Minneapolis Veterans Hosp., Minn.) and B. Mulford. Amer. J. Dig. Dis. 12(3):303-309, 1967.

Pancreatic function in 34 patients with portal cirrhosis was evaluated by measuring the amount of amylase, lipase, phospholipase A, carboxypeptidase, trypsin and chymotrypsin, as well as vol. and bicarbonate conc. of the fluid, secreted into the duodenum during a 30-min. period after the onset of a simultaneous i.v. infusion of secretin (90 U) and pancreozymin (100 U). The values of these parameters were compared with those obtained from 18 normal male controls. Of the 34 men studied, 29 had portal cirrhosis with or without fatty infiltration and 5 had predominately fatty livers with or without mild cirrhosis. Two-thirds of the men had ascites on initial examination and were classified as severe; the remaining third, without jaundice or ascites, were rated as mild or moderate. All consumed excessive amounts of alcohol. Of the 29 with portal cirrhosis, 4 were operated on, 3 for portacaval shunts and 1 for relief of obstructive jaundice due to a swollen nodular pancreas. Approx. 40% of the patients had abnormally low enzyme values and bicarbonate conc. The incidence of abnormally low values was similar for all enzymes, with the possible exception of carboxypeptidase, which was depressed in 7 patients, in contrast to phospholipase A, which was low in 15 patients. Those with severe cirrhosis had significantly poorer pancreatic function, as reflected in secretion of chymotrypsin, phospholipase A and lipase, than did those with mild or moderate cirrhosis. Intercorrelations among the several enzymes measured were significantly positive but not high, similar in all respects to those previously noted in patients without cirrhosis. In two-thirds of the patients with cirrhotic livers, the vol. of duodenal aspirate obtained after infusion of secretin and pancreozymin exceeded the highest vol. previously recorded in the samples from normal men. A low vol. occurred in only 2 of 34 patients.

6567 CALIBER OF THE INFERIOR VENA CAVA IN CIRRHOSIS OF THE LIVER. (E.) Nordenström, B. (Karolinska Hosp., Stockholm) and A. Norhagen. Acta Radiol. [Diagn.] (Stockholm) 6(1):65-80, 1967.

The caliber of the inferior vena cava during respiration was studied radiologically in 13 normal subjects and in 5 with cirrhosis. Simultaneous anteroposterior and lateral views were obtained, and comparisons were made between the width of the subdiaphragmatic part of the inferior vena cava at the level of the liver (T12, or L1) and the width of the part located below the point at which the latter is joined by the hepatic veins (lower margin of L3). In both normals and cirrhotics the inferior vena cava caliber varied considerably in different respiratory phases at all points measured. Max. caliber was reached during expiration, and reflux to hepatic veins regularly occurred during expiration in normals. Caliber variations occurred in the same manner in cirrhotics as in normals, but among the former the vein at the level of the liver appeared to be relatively narrower in comparison to normals than was the portion located below the liver. A few of the cirrhotics closely resembled several normals in absolute diameter of the inferior vena cava at the level of T12 or L1. The most characteristic difference between cirrhotics and normals was the absence of reflux of contrast medium from the inferior vena cava to hepatic veins in cases of advanced cirrhosis. The function of the liver as a blood depot is probably reduced in cirrhosis and, since the liver is fibrotic, it would not be readily compressed by a downward movement of the diaphragm; therefore any evacuation of hepatic venous blood would be unlikely to be produced by respiration. A correlation factor with reference to the size of the subject, as yet undetermined, is thought to be necessary for a comparison of the inferior vena cava caliber between normals and cirrhotics; the size of the vena cava should possibly bear a relationship to the blood vol. of the subject.

6568 ACID-BASE DISTURBANCES IN PATIENTS WIT CIRRHOSIS OF THE LIVER. (E.) Malhaus R. (Minneapolis Vet. Hosp., Minn.), A. Eichenhol and A. Blumentals. Medicine (Balt.) 46(2):185-189, 1967.

A study of 91 patients with Laennec's cirrhosis showed a variety of acid-base disturbances with a reduction in partial pressure of CO_2 as a common denominator. There was an elevation of lactate and pyruvate associated with a reductio in bicarbonate ion conc. pH was in the alkaline or acid range, dependent upon the severity of the existing bicarbonate deficit in the presenc of reduced pCO_2. The mental state of the patien seemed to have no relationship to the acid-base disturbances.

6569 FUNCTIONAL RENAL FAILURE WITH CIRRHOSI THE EFFECT OF PLASMA EXPANSION THERAPY (E.) Reynolds, T. B. (U. Southern California, Los Angeles), F. L. Lieberman and A. G. Redeker Medicine (Balt.) 46(2):191-196, 1967.

Urine flow, plasma vol. and renal function, as reflected in the serum urea nitrogen or creatin clearance, were measured in 24 patients with decompensated alcoholic cirrhosis who had functional renal failure with oliguria. Plasma vol were higher than normal, but were no different from those in patients with ascites who did not have renal failure. Expansion of the plasma vo had some beneficial effect on renal function in 9 of 16, but it had no favorable influence on patient survival. The major causes of death were hepatic failure and gastrointestinal hemorrhage.

6570 ETIOLOGY AND PROGNOSIS OF LIVER CIRRH SIS. (Ger.) Piesbergen, H. (Eilbek German Hosp., Germany) and J. Jungermann. Z. Gastroent. 4(6):345-358, 1966.

Of 327 patients with liver cirrhosis, 228 were men and 99 women, a ratio of 2.3:1. [The numbe of women with cirrhosis has been increasing in Germany; the ratio of men to women in Germany in 1932 was 2.8:1; in 1962 in West Germany 1.7: and in Hamburg 1.8:1.] The av. age of 228 men was 59.7 yr. and of the 99 women, 62.7 yrs. The medical histories of cirrhosis of 150 dead patients indicated a variety of etiologies head by 55 (36.7%) with completely unknown causatio possibly anicteric hepatitis; 50 (33.3%) were due to chronic alcoholism; 36 (24%) had hepati yellow atrophy, chronic cholangitis, lues and neosalvarsan therapy occurred alone, and in combination with the other pathologies named as causes. Of 295 cirrhotic patients 113 (38. were alcoholics ranging from 21 of 21 (100%) tavernkeepers to 10 of 73 housewives (13.7%).

g 61 alcoholics who underwent laparotomy
% had fine knoblike projections from the liver
ace and 19.5% had a coarsely knobbed surface;
g the nonalcoholic patients with cirrhosis
percentages were, resp., 48.5% and 51.5%. Of
150 who died 13 (8.7%) also had diabetes.
01 autopsies, 15 cases of new ulcers were
overed, 17 instances of ulcer scars and 46
rosive gastritis were discovered. Five among
cirrhosis patients suffered ulcer hemorrhage.
death rate (percentage decreased) from time
iagnosis (expressed as yr. in parentheses)
50 cirrhotics was (1) 45%, (2) 63%, (3) 70%,
75%, (6) 82%, (8) 90%, (10) 96%. Of those
ascites, 75% died during the first yr. The
diate causes of death among 101 patients
were hepatic (coma, hemorrhage of varices,
rs, erosive gastritis, etc.); 33% died of
hepatic causes, such as heart attack, cardiac
fficiency, stroke, kidney disease, agranulo-
sis, etc. Esophageal varices were proved in
of 150 cirrhotic patients (69.3 %); hemor-
of these varices occurred in 51 (34%);
as a result of hemorrhage occurred in 31
%). Coma developed in 49 (32.7%) cases;
patients (82%) had ascites.

ALTERED CLEARANCE OF FREE AMINO ACIDS
FROM PLASMA OF PATIENTS WITH CIRRHOSIS
E LIVER. (E.) Iob, V. (U. Michigan Med.
Ann Arbor), W. W. Coon and M. Sloan. J.
Res. 6(6):233-239, 1966.

feeding of an egg-protein mixture (egg white,
dry skim milk, 50 g; dextrose 125 g; and
lled water to a total vol. of 500 ml) or
infusion of a balanced soln. of essential
acids to well-compensated cirrhotic patients
ollowed by a significant change in the rate
earance of several amino acids (isoleucine,
ne, valine and threonine) from the plasma.
pattern was unchanged after portacaval
. The increased clearance of branched-chain
acids and threonine may be secondary to a
ive or absolute deficiency of these essential
ing blocks of protein in the cirrhotic pa-
.

FREE AMINO ACIDS IN LIVER, PLASMA, AND
MUSCLE OF PATIENTS WITH CIRRHOSIS OF
IVER. (E.) Iob, V. (U. Michigan, Ann Arbor),
Coon and M. Sloan. J. Surg. Res. 7(1):41-
967.

mination of free amino acids in liver,
a and muscle was conducted during portacaval
procedure in 10 patients with cirrhosis and
ients with normal liver function undergoing
cystectomy. All patients with cirrhosis had
hypertension. Blood samples were obtained
to anesthesia, while liver biopsy and
e specimens were taken for histologic
nation. A significant reduction in the
of branch-chain amino acids (valine,
ucine, leucine) was found in the muscle

samples of cirrhotic patients as compared to control patients. In addition, conc. of plasma valine were lowered in fasting patients. It is likely that the demand for branched-chain amino acids in cirrhosis results in a secondary depletion muscle amino acid pool as well as protein catabolism and possible muscle wasting. In association with this, an increased uptake of free amino acids from plasma may be in effect stabilizing the amino acid deficiency in the skeletal muscle.

6573 SEVERE RENAL INSUFFICIENCY OF THE ASCITIC CIRRHOTIC. DESCRIPTION, MECHANISM AND TREATMENT OF ITS PRINCIPAL FORMS. (Fr.)(Rev.) Vesin, P. (31 Rue de Moscou, Paris). Schweiz. Med. Wschr. 97(15):477-484, 1967.

6574 THE SURVIVAL TIME OF PATIENTS WITH CIRRHOSIS OF THE LIVER. (Ger.) Brügel, H. (Intern. Med. Clin., Bad Kissingen, Germany). Munchen. Med. Wschr. 109(16):897-901, 1967.

36 IMPORTANCE AND SIGNIFICANCE OF SERUM
TRANSFERRIN AND IRON LEVELS IN
GNOSTIC TESTS AND IN THE COURSE OF ICTEROGENIC
ER DISEASES. (It.) Dematte', P. (Civil
p., Treviso, Italy). Rass. Clin. Ter. 65(3):
-181, 1966.

ermination of serum Fe (modified Barkan
hod and spectrophotometry) and unsaturated
nsferrin, or Fe-building capacity (Ventura
hod) levels were conducted in 62 patients
h various liver diseases accompanied by
ndice. In 47 of 50 patients with acute viral
atitis, serum Fe reached highest levels at
20 days from the onset of the disease and
n progressively decreased; serum unsaturated
building capacity decreased during the first 2
and reached normal levels by day 50. The
aturated Fe-building capacity/serum Fe
tient varied from 1 in early weeks to 1.9 in
er weeks when cure was imminent and proved
be a good indication of the return of liver
ction. High SGPT levels appeared early
rst 5 days) in these patients; serum bili-
in levels were highest at days 3-14 and then
idly fell to slightly higher than normal
ues. In 3 patients with subacute viral
atitis, high serum Fe levels with low un-
urated Fe-building capacity/serum Fe quotient
ss than unity in some cases) were constantly
erved. In 9 patients with obstructive
ndice, serum Fe levels were generally
reased, while SGPT levels were higher than
mal.

7 BEHAVIOR OF SERUM BILIRUBIN PIGMENTS
IN PATIENTS WITH CIRRHOGENOUS HEPATIC
EASE AND JAUNDICE. (CHEMICAL DETERMINATIONS
CHROMATOGRAPHIC ANALYSIS). (It.) Manenti,
(U. Modena, Italy), G. Solmi and L. Spanio.
erva Gastroent. 12(2):53-56, 1966.

ermination of serum bilirubin levels was
ducted by various methods in 18 decompensated
rhotic patients with jaundice. Serum
irubin levels ranged from 3.38-0.45 mg% with
Weber-Schalm method and from 0.5-3 mg% with
Malloy-Evelyn method. A predominance of the
jugated bilirubin fraction, indicative of the
lestatic nature of the jaundice, was observed
h both methods. Thin-layer chromatography of
conjugated fractions revealed the following
centage in 14 patients: monoglucuronides
-50%), diglucuronides (50-40%), and other
ctions (10%). In 4 cases, a greater per-
tage increase was seen in the monoglucuronides
-55%) as compared to the diglucuronides
-35%), with no change in the percentage of
er fractions. The physiopathological
lications of the above findings are discussed.

8 COMPUTER ANALYSIS OF POSTCHOLECYSTECTOMY
BILIARY TRACT SYMPTOMS. (E.) Bodvall, B. (U. Goteborg, Sweden) and B. Övergaard. Surg. Gynec. Obstet. 124(4): 723-732, 1967.

A series of 1,930 patients with cholecystectomies for gallstone disease (with a 98.4% follow-up) was composed of 2 groups of patients of almost equal size but with varying periods of observation: Group 1: 938 patients, 5-9 yr. period of observation; and Group 2: 992 patients, with a 2-yr. period of observation. Patients with postcholecystectomy biliary distress (39.6%) were divided according to the severity of their symptoms into the following categories: dyspepsia, 10.7%; attacks of mild pain, 23.5%; occasional attacks of severe pain, 3%; and severe postcholecystectomy biliary distress, 2.4%. The follow-up series was analyzed in an electronic computer, the factors possibly influencing frequency of postcholecystectomy distress being studied by analyses of multiple variances. Group 1 patients with a long interval between cholecystectomy and follow-up had a significantly higher frequency of distress than Group 2 patients with a short interval; distress appeared at any time after the operation. Women had a significantly higher frequency of distress than men. A decreasing frequency of distress with advancing age at cholecystectomy was found in both sexes, except in women 40-49 yr. old who had the highest frequency (53.5%) of all age groups. Patients with cholecystolithiasis had a significantly higher frequency of postcholecystectomy distress than patients with mild to moderate cholecystitis and severe cholecystitis. The longer the preoperative history, the higher was the frequency of distress. Sex, age, length of precholecystectomy history and type of gallbladder disease were factors which, independently of each other, influenced the frequency of postcholecystectomy biliary distress. The frequency of postcholecystectomy distress was lower the later in the course of acute cholecystitis that cholecystectomy had been performed. Choledocholithotomized patients had a significantly lower frequency of postcholecystectomy distress than did those patients who had not undergone this procedure. Patients with a functioning gallbladder had a significantly higher frequency of postcholecystectomy distress than did those with a nonfunctioning gallbladder. Size or number of stones in the gallbladder did not influence the frequency of distress. Patients with an acalculous, functioning gallbladder had a significantly higher frequency of postcholecystectomy distress than the group with stones in a functioning gallbladder. Gallbladder disease itself, not the presence of a stone, influenced the frequency of postcholecystectomy biliary distress. Patients with dyspepsia and attacks of mild pain considered themsleves improved by the cholecystectomy; these constituted 34.2% of the entire series. Patients with occasional attacks of severe pain (3%) did not present any major therapeutic problems; the reverse was true of the remaining 2.4% with disabling symptoms of severe postcholecystectomy biliary distress.

6589 FIBROSIS OF THE PAPILLA OF VATER. (E.) Acosta, J. M. (Harvard Med. Sch., Boston, Mass.), F. Civantos, G. L. Nardi and B. Castleman. Surg. Gynec. Obstet. 124(4):787-794, 1967.

Pathologic changes in the papilla of Vater were investigated in an unselected series of 38 patients undergoing sphincterotomy for relief of abdominal pain which was thought to be caused by pancreatitis. Of 38 surgical specimens, 22 showed histological abnormalities consisting of varying degrees of fibrosis, pseudopolyp formation and chronic and acute inflammation. Careful retrospective evaluation of these patients suggested that some did not have pancreatitis, while others had associated biliary obstruction. The latter group usually benefited by sphincterotomy. No attempt was made to evaluate or justify use of sphincterotomy as a therapeutic procedure. From these studies it is concluded that pathologic changes frequently occur in such patients, and these changes may be associated with pancreatic obstruction, biliary obstruction, or both.

6590 THE EFFECTS OF BILE DUCT LIGATION AND INFLAMMATION IN THE FETUS. (E.) Holder, T. M. (U. Kansas Med. Ctr., Kansas City) and K. W. Ashcraft. J. Pediat. Surg. 2(1): 35-40, 1967.

Ligation of the common bile duct and inj. of 5% sodium morrhuate, 2% or 5% NaOH, or 5% formalin, either singly or in combination, was carried out in 30 fetal puppies. Histologic sections of the liver, gallbladder and extrahepatic ducts were prepared using eosin and hematoxylin and Gomori trichrome stains, while bilirubin determinations were done using the same semimicro method employed for pediatric patients. The time interval between surgery and birth was 2-6 days in the group of 8 fetal puppies (5 inj. with sodium morrhuate, 2 with duct ligation and 1 sham control) born alive. Survival time lasted from 1 hr.-7 days. Severe necrosis of both the liver and intestine characterized puppies inj. with NaOH and formalin. Three days after morrhuate inj., there was observed variable necrosis and sloughing of the epithelium of the extrahepatic ducts, edema and necrosis of the walls, and focal periportal necrosis of the liver with acute inflammation, especially around the bile ducts. Thickening and narrowing of the main bile ducts were noted along with narrowing of portal areas and bile duct proliferation at 10 days after morrhuate inj. Occasional bile thrombi were also seen. The histologic picture 10 days after bile duct ligation showed total obstruction at the ligation site with marked dilatation proximally, significant bile duct proliferation, some periportal chronic inflammation, generalized bile duct thrombosis in canaliculi and pronounced extramedullary hematopoiesis. In 4 puppies bilirubin determinations demonstrated that bile duct obstruction at birth is associated with significant jaundice.

6591 7-CHLORO-4-HYDROXY-5-INDANCARBOXYLIC ACID (CHIA): A NEW HYDROCHOLERETIC AGENT. (E.) Marshall, F. N. (Dow Chem. Co., Indianapolis, Ind.) and J. P. Long. Arch. Int Pharmacodyn. 165(2):405-409, 1967.

7-Chloro-4-hydroxy-5-indancarboxylic acid was found to be a potent, long-acting, hydrocholeretic agent in anesthetized and unanesthetized dogs, being effective both when admin. i.v. and p.o. It was less potent than dehydrocholic acid during the first 30 min. after admin., but was more potent than florantyrone when total activity was compared over a perio of 5 hr. The LD_{50} after i.v. admin. in rats was 49.0 mg/kg; after intragastric admin., the LD_{50} was 512.9 mg/kg.

6592 NEW CASE OF "CAROLI'S DISEASE" WITH GIANT BILOBAR SEGMENTAL DILATIONS, COMPLICATED BY LITHIASIS AND CURED BY SURGERY. (Fr.) Farah, M., E. Hélou, W. Nasser and W. Tabbara. Rev. Medicochir. Mal. Foie 41(6): 305-328, 1966.

Congenital dilatation of the intrahepatic bile ducts, without cirrhosis or portal hypertensi (Caroli's disease) was diagnosed in a young m (age 19) with intermittent abdominal pain of yr. duration, angiocholitis and a subicteric syndrome. Cholecystectomy, choledochotomy, a transduodenal sphincterotomy with drainage we performed; the postoperative course was uneven ful but 40 days later massive dilatation and lithiasis of some of the extrahepatic bile du were noted. Nephrospongiosis was also found this time. No esophageal varices were presen Since the involvement was apparently localize to several segments of the liver, the patient underwent left hepatectomy with formation of hepatic-choledochal anastomosis in an isolate jejunal segment. There were no signs of recurrence after 3 mo. The 5 other cases of Caroli's disease are reviewed and diagnostic and therapeutic problems are discussed.

6593 ALLERGIC FACTOR IN HEPATOBILIARY MIGRAINE. (Fr.) Bonnet, G. F. (Hotel Dieu, Paris) and P. Nepveux. Sem. Hop (Paris) 43(5):295-299, 1967.

Of 302 patients (259 women, 43 men) with hepatobiliary migraine, 32 (30.5%) showed oth clinical signs of nonallergic nature. In thi

up the av. age was higher (49, compared to
9) and the frequency of cholecystectomy for
hiasis (26%) and arthritis (19.9%) was higher
n in the other patients (10% and 6.7%, resp.).
histamine-latex reaction was allergic in
y 17 of this group (18.4%). The other 302
ients (69.5%) showed 1 or more allergic
ctions, mostly to various foods (especially
ty foods); the histamine-latex reaction was
itive in 168 of these patients (80%). Other
ergens implicated were choleretic substances
ch as alcohol), certain meats (pork, fish,
llfish), bread and high-cellulose leguminous
etables. Of the entire group, 45 (14.9%) had
ergone cholecystectomy for biliary lithiasis
in 1 patient the gallbladder was congenitally
ent. Cholecystography was normal in 50 of
patients studied; gallbladder emptying was
arded in 60 and accelerated in 9.

4 PATHOLOGICAL SIGNIFICANCE OF BACTERIAL
FLORA AND PARASITIC FAUNA OF THE BILE.
.) Gherman, I. (Gastroenterol. Ctr.,
harest, Rumania) and C. Ageelescu. Rev. Int.
at. 16(7):1293-1297, 1966.

5020 bile specimens examined, 445 (7.5%) were
tive for bacteria, the types being colon
illi in 347 (76.22%), enterococci in 53
.6%), Proteus in 44 (9.6%), Staphylococcus in
.2%) and Streptococcus in 2 (0.4%). Parasites
found in 206 specimens (2.4%); Lamblia
estinalis in 203 (98.5%) and Strongyloides
estinalis in 3 (1.4%). In the patients with
teria-positive bile, the primary disease
olved the gallbladder in 52.7%, the intestine
7.6% (duodenitis, enterocolitis, colitis,
), the stomach in 14.8% (gastritis, ulcers,
), the liver in 13% (hepatitis, cirrhosis,
), and extradigestive sites in 1.8%. Bile
cimens positive for parasites were associated
cholecystitis or biliary dyskinesis (not
elithiasis) in 38.2%, intestinal diseases
above) in 30.8%, stomach diseases in 16.2%,
r diseases in 4.4%, and other diseases
luding neuroses and certain allergic
litions) in 10.3%.

5 INVESTIGATIONS ON BILE DIRECTLY FROM
THE LIVER. (Ger.) Jorns, G.
stadt i. Thur. Hosp., Germany). Deutsch.
erdau. Stoffwechselkr. 26(3):138-147, 1966.

mparison is made between gallbladder bile
the bile obtained through a T-drain, i.e.
liver bile. The determination and
uation of liver damage might be better done
liver than gallbladder bile. The
tituents of liver and gallbladder bile are,
., H_2O 97.5%, 85.9%; total solids 2.52%,
%; bile acids 0.93%, 9.14%; mucin and
ring matter 0.53%, 2.98%; cholesterol 0.06%,
%; fat and fatty acids 0.14%, 0.32%; and
ganic salts 0.84%, 0.65%. The vol. of liver
was as high as 1300 ml in the first 24 hr.,

falling to an av. value between 250 and 400 ml/day, with a specific gravity between 1.002 and 1.010, remaining constant in any individual. Bilirubin in 29 of 36 cases was under 100 mg%; in 12 the bilirubin was less than 50 mg%; 6 had values between 100 and 150 mg%; 1 had a value of 189 mg%. The capacity of bile to form emulsions is a function of the bile acid conc. Protein conc. in 28 cases varied from 0.4-1.4 g%. A BSP test given to 1 patient only showed a 50% excretion of the dye into the liver bile in 45 min. 10 days after operation and 97% on the 46th day after operation before the removal of the T-drain. Samples of bile from 30 individuals showed amylase in 23 and trypsin in 6 (5 of these also had amylase). The microscopic examination of liver bile disclosed 6 of 36 samples with no inclusions; 30 had mucous plaques, epithelial and blood cells; 10 had bacteria.

6596 STUDIES ON BILIRUBIN IN BILIARY TRACT DISEASE. (Jap.) Inoue, T. (Kyushu U., Fukuoka, Japan). Igaku Kenkyu (Acta Medica) 36(4):417-443, 1966.

Studies were made on the nature of bilirubin in bile from both the gallbladder and liver, and changes of bilirubin associated with pathological conditions; material included 13 patients with either gastric or duodenal ulcer, or gastric cancer; 8 patients with cholecystitis without calculi; 34 patients with bilirubin stones in the gallbladder and/or common bile duct; 31 patients with cholesterol stones in the gallbladder and/or common bile duct, and 3 patients with pancreatic cancer. Total bilirubin, the ratio of total bilirubin to total solids and indirect bilirubin were measured by the Evelyn-Malloy and Billing methods. Conjugated bilirubin was converted to the amiline azopigment derivative and then fractionated by quantitative thin-layer chromatography into 3 fractions. One fraction was tentatively identified from its chemical composition as a free azopigment, and another fraction as a glucuronide azopigment. In bile from gallbladder without any pathological condition, the total bilirubin content was 3.62 ± 0.12 mg/ml and the ratio of total bilirubin to total solids was 2.21 ± 0.72%. Indirect bilirubin and bilirubin glucuronide comprised 13.0 ± 11.9% and 70.8 ± 6.2% of total bilirubin, resp. A marked decrease in the total bilirubin content and concomitant increase of indirect bilirubin were observed in the gallbladder bile when calculi were present in the common bile duct, while no such changes were found when calculi were only in the gallbladder. In most biliary tract diseases, the glucuronide conjugate constituted 60-70% of the total bilirubin, and no marked difference was found among the various types of diseases. In hepatic bile, indirect bilirubin occupied 25-35% in most of the cases with biliary tract diseases, the figure being a little higher than that in gallbladder bile. Glucuronide conjugate occupied 40-60% in the hepatic bile, which was somewhat less than that in the gallbladder bile.

6597 GALLBLADDER DYSPLASIAS (SO-CALLED CHOLECYSTOSIS). OBSERVATIONS ON 152 CASES. (It.) Gibertini, G. (U. Modena, Italy), R. Lodi, A. Torricelli and E. Zambarda. Ann. Ital. Chir. 42(9/10):707-745, 1966.

A study is made of clinical and therapeutic aspects of a group of gallbladder dysplasias of a predominantly proliferative or degenerative nature (rather than inflammatory or neoplastic), with or without lithiasis, which the authors classify as hyperplastic cholecystosis. Among 2400 gallbladder operations reviewed, 152 (6.33%) such cases (127 women and 25 men) were observed which included cholesterosis (62), adenomyomatosis (45), papillomatosis (11), calcified gallbladder (4), bilocular and pluriseptal gallbladder (19), diverticula (10), and gallbladder duplication with cholesterosis (1). Although their anatomopathological features differ widely, they may be considered a clinical entity from a pathogenetic (congenital or possibly hormonal) and symptomatological (dyspeptic pain characteristic of prelithiasis or some of the more common gallbladder disturbances) viewpoint. Direct and indirect radiological signs are described and their importance in preoperative diagnosis stressed. Treatment of forms without lithiasis and resistant to medication is generally by cholecystectomy. The problem of malignant transformation (especially of polyps) is discussed.

6598 EXPERIMENTAL STUDIES IN THE KINETICS OF THE PLASMA CLEARANCE OF INDOCYANINE GREEN, A SUBSTANCE USEFUL IN DETERMINING HEPATOBILIARY PARENCHYMAL CLEARANCE. (It.) Massari, N. (U. Milan, Italy), C. Santambrogio, F. Civardi, L. Tenconi, C. Guardamagna, S. Negri and S. Procaccia. Rass. Clin. Ter. 65(3): 143-157, 1966.

The kinetics of the plasma clearance of indocyanine green were studied in 97 male rats (Long Island strain) following inj. into the dorsal vein of the foot of 2.5 mg% soln. of the dye and extraction of blood samples from the femoral vein 2-20 min. after the end of the inj. Following inj. into the blood stream, indocyanine green showed an exponential type of plasma clearance and preference for hepatic uptake analogous to that observed with BSP. Thus, the dye can be used in determining hepatic plasma clearance. The mode of plasma clearance and the factors influencing it are similar to those seen with BSP. A dose of 4 mg/100 g of body wt. of indocyanine green was considered appropriate for hepatic function testing and for the 2 principal components of the plasma clearance curve: hepatic uptake and accumulation and biliary excretion.

6599 PERCUTANEOUS CHOLANGIOGRAPHY AND AORTOGRAPHY BY CATHETER TECHNIC.
(E.) Maxwell, J. W. (VA Hosp., Pittsburgh, P
W. C. Davis and F. C. Jackson. Amer. Surg.
33(3):179-182, 1967.

The methods of percutaneous transhepatic
cholangiography and translumbar aortography b
the flexible hubbed cannula technic are described. Both have proved to be a rapid, saf
and effective method of visualizing the bilia
tract and the abdominal aorta and its major
branches (which distribute to major portions
the gastrointestinal tract), and there have
been no mortalities or serious sequelae resul
ing from these procedures. The biliary tree
was successfully visualized in 18 of 20 patie
using the first technic; the remaining 2 were
found to have intrahepatic cholestasis and
needless surgery was obviated. Cholangiograp
enabled the operative procedure to be simplif
in a patient with a high common duct obstruct
demonstrated preoperatively, and in another
case, an intrahepatic ductal obstruction due
tumor not amenable to surgery was observed.
Both the intercostal and subcostal routes hav
been used with equally good results. Percuta
cholangiography is also valuable in establish
ing the exact site of extrahepatic obstructio
preoperatively in patients whose diagnoses ar
reasonably certain, because it facilitates th
operative procedure by reducing the time of
needless and excessive exploration.

6600 AN EVALUATION OF SILICONE RUBBER TU
ING AS A REPLACEMENT OF THE COMMON
BILE DUCT. (E.) Bradley, B. E. (US Naval Me
Res. Inst., Bethesda, Md.), G. C. Vineyard, A
Defalco, D. Lawson and J. R. Hayes. Amer. J.
Surg. 113(4):501-506, 1967.

Silastic tubing (silicone polymer) was used a
replacement of the common bile duct in 19 dog
4 of which had experimentally produced total
obstruction of the common bile duct. Using t
parameters of intermittent serum alkaline
phosphatase and total bilirubin determinatio
and gross and microscopic hepatobiliary tiss
examination, Silastic tubing was found to
function adequately as a bile conduit in 13
(68%) of 19 animals for periods of up to 12
Clogging of the synthetic duct with precipit
bile salts occurred in 1 animal, while in no
was there disintegration of the synthetic
common bile duct. Synthetic duct extrusion
occurred in 4 dogs, and only slight dilatati
of the proximal biliary tree was observed in
of 12 dogs with patent Silastic ducts that
survived until sacrifice. It is concluded t
silicone rubber may be a useful replacement
material for the common bile duct.

6601 ELECTROPHORETIC AND ENZYME CHANGES
CAUSED BY EXPERIMENTAL CHOLESTASIS.
(It.) Arezio, G. (U. Pavia, Italy), G. M. C

G. Gallinotto. Minerva Chir. 21(14):
636, 1966.

rmination of serum protein (electrophoresis)
enzyme levels (transaminase by the Karmen
od; lactic and malic dehydrogenase by the
-Gehm method) was conducted in 16 male
its in which cholestasis was provoked by
ture of the extrahepatic biliary duct. At
10 following surgery, no changes were
rved in serum enzyme levels or in serum
ein fractions. Serum transaminase levels
perceptibly decreased by day 20 and con-
ed to decrease markedly afterwards; by day
dehydrogenase levels were also below normal
to a lesser degree than transaminase levels.
ay 20, progressive decrease of serum albumin
g with an increase in gamma- and beta-
ulins (especially the latter) were observed.
l serum protein levels were not significantly
red. It is concluded that hepatic cells
relatively resistant to bile stasis and that
tic cell injury is the result of other
ors (such as infection or metabolic and
trolyte imbalance) as well. It is also
luded that the changes observed above in
m protein and enzyme levels do not represent
nsitive index of hepatic cell injury.

THE TOLBUTAMIDE TEST IN THE DIAGNOSIS
OF OBSTRUCTIVE JAUNDICE. (It.)
pelli, A. (Riuniti Hosp., Verbania, Italy).
d. Ital. Chir. 15(2):117-123, 1966.

d glucose levels after tolbutamide admin.
i.v. over a 3-min. period) were studied in
ormal subjects (6 men and 4 women; age
) yr.), in 7 patients (6 women and 1 man;
32-63 yr.) with obstructive jaundice caused
allstones, and in 5 patients (3 men and 2
n; age 52-72 yr.) with obstructive jaundice
to pancreatic cancer. In normal controls
blood glucose decrease (49.9%) occurred 40
after inj., with a decrease of 34.9%
rved after 60 min. The decrease in blood
ose levels after 20, 30, 40, and 60 min. was
25.2, 37.3, and 30.5%, resp., in patients
gallstones and 12.2, 21.3, 25.2, and 25.2%,
, among patients with cancer. Results
cate less of a decrease in blood glucose
ls in patients with gallstones as compared
ontrols, and a still lower decrease in
er patients as compared to those with gall-
es as a result of tolbutamide admin. The
ible value of tolbutamide as a test for the
erential diagnosis of the two types of
dice is discussed.

RADIOLOGICAL OBSERVATIONS ON ALTERATIONS
OF THE BILIARY SYSTEM SECONDARY TO
KED BILE FLOW: HYDROHEPATOSIS. (It.)
remoli, A. (U. Bologna, Italy). Radiol. Med.
no) 52(6):513-548, 1966.

ts of retrograde cholangiography are
rted in 22 surgical patients (18 women and
4 men; age 28-76 years) with biliary tract disease caused by progressive blockage of bile flow. Morphological alterations consisted of dilatation and curvature of the hepatic and common bile ducts; formation of a "pseudopelvis", i.e. a dilated area of confluence between the superior bile and hepatic ducts with reduced bifurcation angle; marked dilatation of the zonal intrahepatic ducts; dilatation and "pseudomultiplication" of the secondary intrahepatic ducts. In 5 patients a true picture of blocked bile flow, or hydrohepatosis, was observed. These patients showed very marked and irreversible dilatation of the common bile duct, with little or no curvature, as well as reduced transit of contrast medium and other signs described above to a more marked degree. The pathogenetic mechanism of this condition seems to be similar to that of hydronephrosis, and various interpretations are examined.

6604 THE SPONTANEOUS DISAPPEARANCE OF GALLSTONES. (E.) Arcomano, J. P. (22 High St., Huntington, N. Y.), H. N. Schwinger and J. DeAngelis. Amer. J. Roentgen. 99(3):637-641, 1967.

6605 THE IMPAIRMENT OF SOME FUNCTIONS OF THE LIVER IN ACUTE CHOLECYSTITIS. (Rus.) Struchkov, V. I. (1st Sechenov Order of Lenin Hosp., Moscow), V. S. Vasil'ev and M. P. Rubin. Vestn. Khir. Grekov. 98(1):36-41, 1967.

6606 INTERNAL BILIARY FISTULAS AS A COMPLICATION OF ACUTE CHOLECYSTITIS. (Rus.) Borovyi, E. M. (Rovenki Reg. Hosp., USSR). Sovet. Med. 30(2):97-99, 1967.

6607 CHOLECYSTITIS IN MEN. (Rus.) Korolev, B. A. (Gorki Kirov Med. Inst., USSR) and D. L. Pikovskii. Sovet. Med. 30(2):100-102, 1967.

6608 CAUSES OF DEATH IN ACUTE CHOLECYSTITIS. (Rus.) Biriukova, V. V. (Leningrad Kirov Inst. Postgrad. Med., USSR). Klin. Khir. (Kiev) (3):22-25, 1967.

6609 ACUTE SUPPURATIVE CHOLANGITIS. EXPERIENCE WITH 15 CONSECUTIVE CASES. (E.) Haupert, A. P. (Marquette U. Sch. Med., Milwaukee, Wisc.), L. C. Carey, W. E. Evans and E. H. Ellison. Arch. Surg. (Chicago) 94(4): 460-468, 1967.

6610 ACUTE PAPILLO-ODDITIS AS A CAUSE OF MECHANICAL JAUNDICE. (Bul.) Khaitova, A. and P. Pomakov. Vatr. Bolesti 5(1):120-126, 1966.

6611 TORSION OF THE GALLBLADDER. (E.) Rietberg, M. (State U., Groningen, Netherlands). Arch. Chir. Neerl. 18(3):195-201, 1966.

6612 CHOLELITHIASIS IN CHILDHOOD. (It.) Casagrande, A. (C. Cantu Hosp., Abbiategrasso, Italy) and A. Fiocchi. Gazz. Sanit. (Milano) 37(7-8):357-360, 1966.

6613 HEMOBILIA. (Pol.) Karwowski, A. (2nd Surg. Clin., Warsaw) and I. Suszczewska-Fischerowa. Pol. Przegl. Chir. 39(3):230-233, 1967.

6614 ABILITY OF A NEW LONG-ACTING SULFONAMIDE FANASIL TO PASS THRU THE BILE AFTER ORAL APPLICATION. (Ger.) Stauber, R. (Leoben Hosp., Austria). Wien. Klin. Wschr. 79(15):269-273, 1967.

6615 ROENTGENOLOGICAL EXPLORATION OF THE BILIARY TRACT PRIOR TO AND DURING THE OPERATION. (Rus.) Gadzhiev, A. S. (Kalinin Med. Inst., USSR) and M. N. Teben'kov. Sovet. Med. 30(2):94-97, 1967.

6616 LAPAROSCOPIC CHOLANGIOGRAPHY. (Rus.) Vinogradov, V. V. (Lumumba Friendship U., Moscow), V. I. Kochiashvili and F. A. Bragin. Klin. Khir. (Kiev) (3):25-28, 1967.

6617 DIFFICULTIES AND ERRORS IN DIAGNOSIS OF THE SYNDROME OF ELONGATED STUMP OF THE CYSTIC DUCT AFTER CHOLECYSTECTOMY. (Pol.) Dobrowolski, J. (1st Surg. Clin., Zabrze, Poland), M. Glinski and E. Szlachta. Pol. Przegl. Chir. 39(3):239-243, 1967.

6618 INTRAOPERATIVE CHOLANGIOGRAPHY. (Ger.) Plettner, U. (Region. Hosp., Dessau, Germany). Zbl. Chir. 92(12):448-450, 1967.

6619 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. (E.) Mulero, H. L. (Wayne State U., Dearborn, Mich.) and H. P. Carvalho. Amer. J. Gastroent. 47(2):113-123, 1967.

6620 THE ANATOMICAL DIAGNOSIS OF JAUNDICE BY PERCUTANEOUS CHOLANGIOGRAPHY AND ITS INFLUENCE ON TREATMENT. (E.) Thorbjarnarson, B. (New York Hosp.-Cornell Med. Ctr., N. Y.). Surgery 61(3):347-354, 1967.

6621 SEGMENTAL PORTOGRAPHY AND TRANSHEPATIC CHOLANGIOGRAPHY USING A LAPAROSCOPIC TECHNIC. (Ger.) Wannagat, L. (Metab. Clin., Bad Mergentheim, Germany). Verh. Deutsch. Ge
Inn. Med. 72:678-682, 1967.

6622 FREQUENCY OF CHOLECYSTOSIS IN SUBJECTS SUBMITTED TO RADIOLOGICAL INVESTIGATION OF THE GALLBLADDER. (It.) Cosmacini, G. (Milan Gen. Hosp., Italy) and F
Costa. Minerva Radiol. 12(3):83-87, 1967.

6623 ETIOLOGY AND TREATMENT OF RECURRENC
AFTER BILE DUCT SURGERY. (Rus.) Kurbangaleev, S. M. (1st Pavlov Leningrad Med
Inst., USSR) and M. B. Rall. Vestn. Khir. Grekov. 98(2):20-24, 1967.

6624 INDICATIONS FOR SURGERY AND PROGNOS
IN BILIARY ILEUS. (Ger.) Enderlin
F. (U. Clin. Basel, Switzerland) and A. Nadja
Praxis 56(16):541-546, 1967.

6625 LATE RESULTS OF CHOLEDOCHAL SURGERY
(Ger.) Lázár, D. (City Hosp., Nagykanizsa, Hungary), J. Horváth and A. Pölöskey. Acta Chir. Acad. Sci. Hung. 8(1): 53-60, 1967.

6626 POSTOPERATIVE HERNIAS AFTER SURGERY
FOR ACUTE CHOLECYSTITIS. (Rus.) Karnov, M. M. (Leningrad Dzhanelidze Res. Ins
Emergency Treatment, USSR). Vestn. Khir. Gre
98(3):24-26, 1967.

6627 USE OF TRANSHEPATIC INTUBATION IN BILIARY STRICTURE REPAIR. (E.) Burrows, L. (Mount Sinai Hosp., New York, N.
and A. E. Kark. Amer. J. Surg. 113(3):409-4
1967.

6628 HEPATIC LESION IN EXTRAHEPATIC BILIARY TRACT DISEASES. (Fr.) Verme, G. (U. Sienne, France) and M. Gentili
Rev. Int. Hepat. 17(1):15-33, 1967.

6629 INJURIES TO BILIARY TRACTS OCCURRI
DURING OPERATIVE PROCEDURES ON THE
(Pol.) Spruch, T. (1st Surg. Clin., Lublin, Poland) and L. Kurylcio. Pol. Przegl. Chir. 39(3):216-218, 1967.

6630 SURGICAL MANAGEMENT OF CHOLEDOCHOLITHIASIS. (E.) Stefanini, P. (U. Rome). J. Abdom. Surg. 9(5):142-146, 19

6631 EARLY OPERATIVE TREATMENT OF ACUTE
CHOLECYSTITIS. (Pol.) Berner, J.
(3rd Surg. Clin., Lodz, Poland) and A. Sołty
Wiad. Lek. 20(5):429-431, 1967.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

Use of Funds for printing this publication
approved by the Director of the Bureau of
the Budget on August 26, 1965

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $8.50; foreign $10.75; and $1.00 per single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by Index Medicus. For journals not covered by Index Medicus, the abbreviations (with some modifications) found in World Medical Periodicals, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

GENERAL

632 ULTRAVIOLET-INDUCED COLICINES OF
Escherichia coli FROM THE NORMAL HUMAN
NTESTINE. (E.) Young, V. M. (NIH, Bethesda,
d.), W. C. Branche, Jr., D. M. Kenton and M. R.
ee. *J. Path. Bact.* 92(2):303-311, 1966.

trains of *Escherichia coli*, obtained from fecal
ultures taken monthly for 6 mo. from 5 persons,
ere exposed to UV radiation to induce production
f colicines. Of 259 strains recovered, 75
ielded colicines, whereas 159 of these had pre-
iously been observed to produce colicines without
nduction. Of colicines induced from *E. coli*
trains obtained from 3 people with the least
table flora of *E. coli*, 13.9% of the colicines
ere active against the parent *E. coli*. Induced
olicines were active against 15% of 234 randomly
elected indicator strains of *E. coli*. One indica-
or strain was sensitive to 69.3% of induced
olicines, a sensitivity similar to that of the
nown indicator *E. coli*. Colicinogen activity
ften varied in irradiated broth cultures in-
ubated for 3.5 and 24 hr. at 37°C. Colicine
roduction was not constant in organisms of the
ame serotype isolated from the same individual
t different times. Although colicinogeny appears
o be associated with the ability of some strains
f *E. coli* to maintain themselves as dominant
esidents in the human intestine, the role of
nduced colicines in the ecology of intestinal
lora remains undetermined.

633 EXTRAVASCULAR SHORT-CIRCUITING OF OXYGEN
INDICATING COUNTERCURRENT EXCHANGE IN
HE INTESTINAL VILLI OF THE CAT. (E.) Kampp, M.
U. Goteborg, Sweden), O. Lundgren and N. J.
ilsson. *Experientia* 23(3):197-198, 1967.

ifferent blood mixtures including oxygenated
lood, blood containing methemoglobinemic cells,
nd a mixture of the 2 preparations were inj.
nto the superior mesenteric artery of the cat
ollowed by measurement of time of appearance
f O_2 in venous blood. Oximeter tracings were
btained from the venous outflow of denervated
ejunal segments. Results demonstrated that O_2
ppears approx. 1-2 sec. before methemoglobinemic
ells. Increased O_2 saturation of hemoglobin was
ndicated by an initial upward deflection approx.
.5 sec. after inj. which was followed by a down-
ard deflection at 4 sec. after inj. indicating
he appearance of methemoglobinemic cells in the
enous blood. Venous outflow measured concurrently
ith both inj. was 41 ml/min. per 100 g of tissue.
mixed preparation resulted in an initial upward
eflection after approx. 2.5 sec. followed
mmediately by a downward deflection having a
lightly greater magnitude. The longer appearance
ime of methemoglobin RBC compared to oxygenated
BC suggests that O_2 may diffuse and short circuit
xtravascularly in the intestinal villus, probably
etween the ascending and descending limbs of the
ascular loop.

6634 AGE AND THE CELL CYCLE OF THE MOUSE COLONIC EPITHELIUM. (E.) Thrasher, J. D. *Anat. Rec.* 157(4):621-626, 1967.

6635 CELL PROLIFERATION STUDIES IN THE INTESTINAL EPITHELIUM OF THE RAT. HYPERPLASIA DURING LACTATION. (E.) Cairnie, A. B. (Inst. Cancer Res., Sutton, Surrey, England) and R. E. Bentley. *Exp. Cell Res.* 46(2):428-440, 1967.

6636 RELATIVE CHANGE IN GASTROINTESTINAL WEIGHT DURING LACTATION. (E.) Spencer, R. P. (Yale U. Sch. Med., New Haven, Conn.). *Amer. J. Dig. Dis.* 12(5):527-528, 1967.

6637 EFFECTS OF EPINEPHRINE AND NOREPINEPHRINE ON THE MESENTERIC CIRCULATION OF THE CAT. (E.) Ross, G. (U. California, Los Angeles). *Amer. J. Physiol.* 212(5):1037-1042, 1967.

6638 INFLUENCE OF A MIXTURE OF CHEMICAL RADIOPROTECTORS ON THE CELLULAR RENEWAL IN THE DUODENUM OF MICE. (E.) Maisin, J. R. (Nucl. Energ. Stud. Ctr., Mol, Belgium) and M. Lambiet. *Nature (London)* 214(5086):412-413, 1967.

6639 THE SEPARATION OF THE α-GLYCEROPHOSPHATE AND MONOGLYCERIDE PATHWAYS IN THE INTESTINAL BIOSYNTHESIS OF TRIGLYCERIDES. (E.) Johnston, J. M. (U. Texas, Dallas), G. A. Rao and P. A. Lowe. *Biochim. Biophys. Acta* 137(3): 578-580, 1967.

6640 INTERNAL PRESSURES OF SMALL ARTERIES AND LYMPH VESSELS OF THE EXPOSED RABBIT MESENTERY WITH A PRACTICAL METHOD FOR MEASUREMENT. (E.) Mori, K. (Nagoya City U. Med. Sch., Japan), M. Takada, F. Kato, K. Torizawa, I. Chaya and K. Hotta. *Nagoya Med. J.* 12(4):261-264, 1966.

6641 BEHAVIOR AND METABOLIC SIGNIFICANCE OF PLASMA FREE FATTY ACIDS AFTER TOTAL PANCREATECTOMY. (It.) Siri L. D., G. (U. Pavia, Italy). *Chir. Ital.* 17(6):685-693, 1965.

6642 ELECTRON MICROSCOPIC ALTERATIONS OF SUBMAXILLARY GLAND PRODUCED BY ISOPROTERENOL. (E.) Takahama, M. (Mt. Sinai Hosp., New York, N. Y.) and T. Barka. *J. Ultrastruct. Res.* 17(5-6):452-474, 1967.

6643 HISTOCHEMICAL REACTIONS OF THE ENTEROCHROMAFFIN CELLS AND THE 5-HYDROXYTRYPTAMINE CONTENT OF THE MAMMALIAN DUODENUM. (E.) Penttilä, A. (U. Helsinki). Acta Physiol. Scand. 69(Suppl. 281):7-77, 1966.

Formaldehyde-induced fluorescence and 5 staining reactions were studied in the duodenal enterochromaffin cells of the sheep, cow, pig, guinea pig, mouse, rat and rabbit. The former was the most specific and sensitive, the argyrophil method the most effective of the stains. All fluorescent enterochromaffin cells were also argyrophil. Argentaffin reaction stained all the enterochromaffin cells in the sheep, cow, pig and guinea pig, but only some in the other species. Only in pig and guinea pig were ferric ferricyanide, diazo coupling and indophenol positive in all fluorescent enterochromaffin cells, but were indophenol-negative in the other animals. The number of fluorescent enterochromaffin cells/mm^3 duodenal tissue and the serotonin conc. (µg/g duodenal tissue) were determined from adjacent duodenal specimens taken near the pylorus of the 8 adult species and from developing duodenum of guinea pig and rat. Enterochromaffin cells were numerous in the guinea pig and sheep, few in the horse, moderate in the others; serotonin conc. followed the same pattern. The correlation between enterochromaffin cell number and serotonin conc. was highly significant. In developing guinea pig, levels were similar to the adult; in developing rat, levels were lower than adult (reached in 24-32 days). In the guinea pig, reserpine had no effect on argyrophil, abolished the diazo coupling and indophenol reaction more effectively than argentaffin and ferric ferricyanide, had a weak effect on fluorescence. Enterochromaffin cell number and serotonin conc. varied together. In the adult rat, reserpine caused no histological changes in enterochromaffin cells, but in the newborn rats weakened the fluorescence. The largest doses reduced the serotonin conc. significantly, without causing any alterations in the enterochromaffin cell number of adult or newborn rats. Chronic cortisone treatment increased both parameters in the newborn rat, but fluorescence was unaffected. It is concluded that in the above mammal species the enterochromaffin system is morphologically and functionally similar and that there is only 1 principal type of enterochromaffin cell in adult mammals.

6644 HISTOCHEMICAL STUDY OF PANETH CELL GRANULES IN MICE. (It.) Riva, A. (U. Cagliari, Italy). Arch. Ital. Anat. Embriol. 71(3):191-203, 1966.

In the jejunum of newborn to 8-mo.-old, male, albino Swiss mice, zymogenic granules found in Paneth cells showed an enveloping structure which had all the characteristics of a sialomucin, rather than a perigranular halo. The structure was digested by trypsin, although the central portion, which it enveloped, was not. From the time of their first appearance, 11-12 days after birth, these granules consisted of a central, periodic acid Schiff-positive portion, apparently lacking acidity, plus the sialoprotein, periphera "envelope" described, with essentially identical histochemical characteristics irrespective of the age of the animal from which they were derived.

6645 THE ORIGIN, DEVELOPMENT AND DIFFERENTIA TION OF BRUNNER'S GLANDS IN THE RAT. (E.) Krause, W. J. (U. Iowa, Iowa City) and C. R. Leeson. J. Anat. 101(2):309-320, 1966.

Studies on 270 prenatal (1 group of 8/day of 16-21-day-old embryos) and postnatal (daily from birth-10 days; weekly from 2-9 wk.; 1 group each, 24 and 33 wk.) Long-Evans rats are reported. Longitudinal ridges appear in the stratified epithelium of the duodenum of 17-day embryos, a time when epithelium is in a stage of cell proliferation. At this time vacuolization appears in epithelium of pylorus and duodenum and is followed by evagination of connective tissue (lamina propria). Duodenum of the 18-day embryo shows invagination of epithelium to initiate formation of Brunner's glands and crypts of Lieberkühn. At this time goblet cells and villi appear and in the lamina propria myoblasts differentiate to form a primitive muscula mucosa, most marked in relation to pyloric mucos Brunner's glands arise primarily from bases of crypts from the 19-day embryo until the end of the second postnatal mo. Glands begin as buds which proliferate downward and branch to give rise to tubules and to a duct system. The gland are less well developed on the side associated with the pancreas, probably due to vascular deficiency. The secretory product of component cells (periodic acid Schiff-positive and resistant to saliva or animal diastase digestion) accumulates in the region of the Golgi apparatus and is then released to the apical portion of the cell where it accumulates. That the secretory process may be apocrine is suggested by the irregular disrupted appearance of the apical border of cells when the secretory produc is expelled. It is suggested that Brunner's glands in the rat be thought of as modified extensions of the crypts of Lieberkühn.

6646 ARTERIAL VASCULARIZATION OF THE ESOPHAGEAL-GASTRIC JUNCTION AND ITS IMPLICATIONS WITH RESPECT TO FUNCTION. (Por.) Ferraz de Carvalho, C. A. (U. Sao Paulo Fac. Med., Brazil). Rev. Hosp. Clin. Fac. Med. S. Paulo 21(3):113-128, 1966.

Arterial vascularization of the esophageal-gastr junction was studied in 92 human preparations, of which 52 were from subjects aged 12-90 yr. and 40 from newborn infants. Arteries rising from the gastric subserosa penetrated the muscle sheath in the zone of esophageal-gastric epithelial transition to reach the submucosa, forming an arterial net which appeared to be essentially independent of either the gastric or the esophageal arterial circulations. Each of these penetrating rteries also appeared to vascularize an esentially independent territory. The particular disposition observed suggested that the muscle heath, in turn, may act as a regulatory mechanism, ontrolling arterial blood flow in this area. pprox. 2 cm distal to the area, the arteries howed a system of very delicate anastomoses with he rest of the gastric submucosal arterial net nd a similar anastomotic system was demonstrable n the abdominal portion of the esophagus, above he transitional area. It is concluded that the ascular pattern of the esophageal-gastric transiion zone, especially in the gastric segment, s similar to that of the lesser curvature of the tomach where the arterial supply is also mainained by arteries rising from the subserosa and enetrating the muscle sheath. It is also sugested that these penetrating arteries of sophageal-gastric junction may act as one of the echanisms involved in avoiding gastroesophageal eflux, by inducing turgescence and spontaneous nfolding of the mucosa.

647 A NOTE ON THE "DARK" CELLS OF THE EXOCRINE PANCREAS. (E.) Ichikawa, A. Tohoku U. Sch. Med., Sendai, Japan). Nippon oshikigaku Kiroku (Arch. Histol. Jap.) 28(1): 7-88, 1967.

ariations in the fine structure of the exocrine ancreatic cells from the guinea pig were corelated with different fixative technics including mmersion (phosphate-buffered osmium tetroxide-, -collidine-buffered osmium tetroxide made sotonic with sucrose and cacodylate-buffered lutaraldehyde soln.), dripping (phosphate-uffered osmium tetroxide) and inj. (Millonig's oln.). Pancreatic specimens from the mouse ere fixed by immersion only. Dark cells were enerally limited to the innermost sector after mmersion fixation using glutaraldehyde soln. ut became generally scattered after osmium etroxide fixation. Dark cells were more prevlent in phosphate buffered than collidine-uffered preparations as well as in the guinea ig preparations generally. Fixation by ripping resulted in "light" cells limited to he superficial and "dark" cells confined to he deeper sectors. Inj. fixation produced light" cells spreading from inj. point, while dark" cells were observed outside this area. ark cells showed no fine structural differences rom "light" cells and are probably related to he severe dehydration of the cytoplasm resulting rom fixation. In addition to the "dark" cell tself, both "central condensation" of zymogen ranule and unhomogeneous agglomeration of the uminar contents are considered artifacts reulting from sample preparation.

6648 A METHOD FOR THE CYTOLOGIC STUDY OF THE INTESTINAL MUCOSA IN SPECIMENS OF ISOLATED EPITHELIUM. (It.) Malacarne, P. (U. Ferrara, Italy) and G. L. Castoldi. Arch. Ital. Mal. Appar. Dig. 33(1):27-36, 1966.

Following conventional washing and shaking in physiologic saline soln., fragments of rat intestine approx. 1 cm long were transferred to a combination of 10 ml isotonic saline plus 0.1 ml glacial acetic acid and agitated for approx. 1 min., resulting in complete separation of the mucosa from the epithelium proper. Following approx. 5 min. exposure to a fresh environment of acid soln., as above, violent agitation was continued until a dense, macroscopically visible suspension of epithelial fragments was obtained, following separation of the villous from the intermediate epithelium. Repetition of the procedure made it possible to eliminate all remaining scraps of supportive tissue, recognizable by their whitish color, and to collect the villous epithelial fragments by centrifugation, resuspending them in physiologic saline. Careful histologic examination confirmed that only the connective structure composed of villi remained, with its normal epithelial coating entirely intact and showing no evidence of either anatomical or structural changes attributable to the procedure. It was possible to demonstrate all cellular elements perfectly, as a whole or individually, permitting highly accurate cytomorphologic, histochemical and quantitative studies to be made.

6649 LYMPHATIC AND BLOOD VESSELS OF THE HUMAN PARIETAL PERITONEUM AND ITS CONSTRUCTION. (Ger.) Juldaschew, I. J. (1st Moscow Med. Inst.). Anat. Anz. 120(2):127-142, 1967.

In injected specimens of human peritoneum, the upper network of lymph capillaries was found underneath the mesothelium and in the upper portion of the collagen network of the peritoneum. The deeper capillary network and the larger lymphatic channels were found in the deeper collagen elastic layer. The fibers of the upper collagen layer were approx. parallel to the orientation of the upper lymphatic capillaries. The plexi of the lymphatic vessels lay in the subserosal fatty layers. Blood capillaries and plexi were seen at various depths in the peritoneal tissues and the subserosal fatty layer. The structure of the lymph node and blood capillaries depended on the functional status of the peritoneum, which varied from 1 place to another and also changed with age. Small mesothelial cells and large lymph capillaries seemed to be combined in areas of intensive absorptive capacity. The close association of lymph and blood capillaries raises doubts of the existence and functional significance of the so-called serous hemolymphatic barrier.

6659 IRON ABSORPTION AND EXOCRINE PANCREAS FUNCTION. (Ger.) Dietze, F. (Charity Clin., U. Berlin, Germany), G. Brüschke, E. Lindenau, A. Rückert and I. Stockov. Deutsch. Gesundh. 22(7):289-292,.1967.

In normal subjects, p.o. admin. of a pancreas extract containing protease, amylase and lipase (Mezym forte, 18 + 11 + 2 U/tablet, resp.) significantly inhibited the absorption of exogenous Fe. Release of the inhibitory substance was prevented by coating the tablet with an acid-proof substance; the inhibitory principle began to exert its effect after about 1 hr. in the stomach, as shown by the greater inhibitory curve obtained after crushing the tablets. Heating the pancreatic extract (10 min. at over 100°C in aqueous soln.) reduced or neutralized its inhibitory activity; the extent of inhibition of Fe absorption could not be increased by increasing the dosage of the extract. The significance of pancreatic factors in Fe absorption is discussed, with particular reference to the possible etiology of hemochromatosis (possibly a genetic anomaly of pancreatic function, the normal factor(s) inhibiting Fe absorption being absent).

6660 EXPERIMENTAL STUDIES ON IRON ABSORPTION. (Ger.) Kuss, B. (U. Bonn, Germany). Aerztl. Forsch. 20(2):60-71, 1966.

The absorption of Fe was studied in preliminary trials by (1) i.p. inj. of 3.4 mg of Fe as $FeCl_2$ in 5 ml of physiological saline in the guinea pig which has a normal serum level of about 350 μg%; (2) the enteral inj. of the same dose as in (1). Serum levels of Fe increased n both i.p. and enteral inj. more rapidly from the peritoneal cavity (to 619 μg% in 2 min. and to 775 μg% in 3 min.) than from the intestine (391 μg% in 10 min. and 422 μg% in 20 min.). The absorption of Fe through the small intestinal wall was tested in segments of the small ntestine 3-4 cm long, everted, and with both ends tied off; Fe was placed in the medium surrounding the segment. After an interval the fluid content of the segment was removed and the Fe conc. determined. All parameters were kept as constant as possible. The uptake of ferrous and ferric iron was measured by spectrophotometer n jejunal segments of the guinea pig at pH 6, 6.8, 7.2 and 7.8 after different intervals of ime. The most rapid absorption of ferrous iron occurred at pH 7.2, the rate decreasing sharply at higher and lower pH. The absorption of ferric iron was somewhat more rapid than that of ferrous iron; the rate changes in response to pH were similar to those for the divalent ion. he rate of absorption in relation to Fe conc. n the medium resulted in a curve closely esembling the oxygenation curve of hemoglobin; t an Fe conc. of 50 μg the absorption was 95% of max. and at 100 μg about 98% of max. Absorption as influenced by different types of buffer pairs and by temperature was also studied as well as the effect of dinitrophenol. Active transport of ferrous iron in the jejunum of the golden hamster is reported.

6661 IRON ABSORPTION AND RETENTION IN MAN. (E.) Boender, C. A. (State U., Utrecht, Netherlands), E. Mulder, J. E. Ploem, J. De Wael and M. C. Verloop. Nature (London) 213(5082):1236-1237, 1967.

A test dose of 15 μc ^{131}Br and 170 mg $BaSO_4$, 5 μc ^{59}Fe and 1 mg Fe in the form of $FeSO_4$, 10 mg ascorbic acid and 2 g carmine red was admin. to 3 normal subjects with normal hemograms, normal serum Fe conc. and serum Fe saturation percentages; 2 patients with sideropenic anemia; 2 with Fe overload. The data indicated that $BaSO_4$ was not absorbed. In the Fe-deficient patients ^{59}Fe disappeared from feces only slightly later than ^{131}Br. Absorption of Fe is believed to occur within 2 hr. The proportionate radioactivity of ^{59}Fe and ^{131}Br in feces showed the coefficient always to be lowest in the first sample to show carmine red; in later samples the coefficient increased. This is assumed to be related to absorption of Fe by epithelial cells which are soon lost into the intestinal lumen. The ratio of ^{59}Fe to ^{131}Br increased least in sideropenic anemia patients. In normal and Fe-overload patients ^{59}Fe was present in feces long after ^{131}Br was no longer demonstrable. Normals retained 9-27% of Fe compared to 20-47% absorbed after 10-15 days; Fe-deficient patients 52-77% compared to 53-83% absorbed; and Fe-overload patients 9-12% compared to 23-29% absorbed. The data indicate that in man more Fe is normally absorbed than is ultimately retained in the organism. Only in sideropenic patients is retention nearly as great as absorption. The procedure may be useful for diagnostic purposes without the need for quantitative collection of feces.

6662 STUDIES OF THE SITE OF ACTION OF DEFEROXAMINE. (E.) Brown, E. B. (Washington U. Sch. Med., St. Louis, Mo.), Y.-F. Hwang and J. W. Allgood. J. Lab. Clin. Med. 69(3):382-404, 1967.

Experiments were performed to examine the effect of deferoxamine on (1) Fe in storage depots, (2) Fe release from storage depots, (3) Fe in the process of absorption, and (4) Fe excretion in the bile and feces. Neither Fe dextran nor recently deposited hemoglobin Fe was mobilized from storage depots in significant amounts. Experimentally increasing or decreasing release of Fe from storage depots by phlebotomy or inj. of pyrogens had little effect on deferoxamine-induced urinary Fe excretion. Fe excretion induced by deferoxamine was poorly correlated with Fe stores or with the ferrokinetic measurements in patients with various types of Fe overload. Max. daily urinary Fe excretion induced by the drug was always less than the calculated daily plasma Fe turnover. Parenteral inj. of deferoxamine had little effect on Fe in the process of intestinal absorption. Biliary Fe excretion was slightly enhanced by deferoxamine but apparently does not account for the high fecal excretion in some subjects. No unique site where deferoxamine chelates Fe before its excretion could be identified. Increased Fe stores serve as the ultimate source of iron excreted after deferoxamine inj.; the immediate source of Fe is unknown.

6663 DETERMINATION OF THE INTESTINAL ABSORPTION OF CALCIUM, USING ^{47}Ca.

(Sp.) Litvak, J. (U. Chile, Santiago), E. Oberhauser, A. Vukusic, I. Zanzi, O. Lopez, I. Alliende and R. Armendaris. Rev. Med. Chile 94(7):415-419, 1966.

Among 18 normal, fasting subjects receiving $^{47}CaCl_2$ (20-40 μc, p.o. in milk), mean serum conc. per 1.73 m^2 body surface, expressed as percentages of the total dose found at 1, 2, 3 and 4 hr. after admin., were 6.4%, 10.0%, 12.4% and 12.5%, resp. Among 11 patients with disorders affecting the intestinal absorption of Ca (4 had malabsorption syndrome; 5 had chronic kidney disorders; 2 had osteomalacia resistant to vitamin D), comparable tabulations were 1.7%, 2.8%, 3.1% and 3.1%, resp. In 2 normal subjects and 2 of 3 patients with kidney disease in whom the test was repeated after pretreatment with vitamin D (100,000 U/day for 3 days, i.m.) serum conc. of Ca were increased significantly. Urinary excretion studies, made for all subjects at 4 and 24 hr., yielded largely comparable but less distinct results, with some overlapping between the patient and control groups. It is concluded that the method described represents a simple and highly reliable test for intestinal absorption of Ca.

6664 ABSORPTION OF RADIOACTIVE-TAGGED SUBSTANCES FROM URINARY BLADDER AND ISOLATED SMALL INTESTINAL LOOPS.

(Ger.) Strohmenger, P. (U. Munster, Germany) and H. Sack. Urol. Int. 21(16):538-548, 1966.

Isolated 25-cm long loops were constructed from the lower ileum in dogs; the proximal end was closed; the distal end was brought out to the abdominal surface through an extra incision; intestinal continuity was re-established by a side-to-side anastomosis. Radioactive tracer substances in soln. were instilled into the intestinal loops or into the urinary bladders by well-fitted catheters. Absorption of Ca as $^{45}CaCl_2$ from the intestinal loops was 80% in 90 min. Absorption was rapid and was close to max. within 60 min. No absorption of Ca from the urinary bladder was recorded by the scintillation counter. $NaH_2{}^{32}PO_4$ was 90% absorbed by the small intestine within 90 min. No absorption of ^{32}P occurred in the urinary bladder. Lack of absorption of Ca and phosphate in the urinary bladder favors precipitation of these substances in the upper urinary passageways. Absorption of inulin and paraaminohippuric acid was also tested in intestinal loops and urinary bladders; these urinary clearance substances were marked with radioactive iodine. A complication arose with the labeled inulin which lost radioactive iodine related to pH, from 10% at pH 5 to about 20% at pH 7.2 and 43% at pH 9. No actual absorption of inulin took place either from the intestine or the urinary bladder. Paraaminohippuric acid was absorbed in the intestine (97-99%) and also from the urinary bladder (33-39%) unrelated to pH.

6665 THE EFFECT OF CARDIOTONIC STEROIDS ON THE INTESTINAL ABSORPTION OF ACTIVELY TRANSPORTED AND DIFFUSING SUBSTANCES AND ON THEIR RELATIONSHIP TO Na$^+$ CONCENTRATION AND Na$^+$ TRANSPORT.

(Ger.) Lauterbach, F. (Madaus Biol. Inst., Koln-Merheim, Germany). Biochim. Biophys. Acta 135(2):273-285, 1967.

Absorption, diffusion and transport of Na, K, and Ca, glucose, urea and water in the presence of different conc. of the cardiac glycoside, convallatoxin, were studied in the wall of isolated, everted 5-cm long segments of the small intestine of the rat and guinea pig. A balanced, buffered, isotonic salt soln. containing glucose was used for incubation. When the ionic conc. was altered, isotonicity was maintained. The segment, containing 1 ml of the unaltered salt soln., tied at both ends, was placed in 20 ml of soln. maintained at 37°C in an atmosphere of O_2 for a period of 45 min. Conc. of substances in the incubation fluid were analyzed. The transport of substances in the intestinal wall of the rat was unchanged in the presence of convallotoxin up to 0.4 mM. In the guinea pig increasing conc. of glycoside caused an increasing but proportional inhibition of all absorption processes determined. The ratios of the absorbed substances, water, glucose, Na and Ca remained constant. The glycoside had no effect upon the passive diffusion of urea across the wall of the guinea pig intestine. It is concluded from the results that the cardiotonic steroid diminished intestinal transport processes by inhibiting the transport of the Na and that the maintained constant ratio of Na to the other substances then must reduce the amount of these other substances passing through the intestinal wall.

6666 WATER AND ELECTROLYTE CONTENT OF HUMAN ILEOSTOMY FLUID AFTER d-ALDOSTERONE ADMINISTRATION.

(E.) Levitan, R. (New England Med. Ctr. Hosp., Boston, Mass.) and K. Goulston. Gastroenterology 52(3):510-512, 1967.

ix balance studies were performed on 4 patients 23-40 yr.) with established well-functioning leostomies. All had a total colectomy and leostomy for idiopathic ulceritis, were in good ealth, and had salt and fluid intake maintained t 9 g NaCl and 2600 ml/day, resp. After 3 onsecutive control days, 2 mg D-aldosterone as admin. (i.v. in 50 ml 5% dextrose for 20 min.) n the morning of each of the next 3 days and alance studies were continued 3-4 additional onsecutive days after the last aldosterone inj. ollections (24 hr.) of ileostomy excreta were nalyzed for vol. and wet wt.; Na and K conc. in upernatant fluid were analyzed by flame hotometry; Cl was determined by potentiometric itration (all in duplicate). Values in control eriods before and after aldosterone were compared by variance analysis with the study periods or individuals separately and for the entire roup. Both methods of analysis showed no ignificant alterations in vol., wet wt., or Na, , and Cl conc. in the study period as compared ith the controls. Electrolyte output was also naffected by hormone admin. Although the mean alues for Na output decreased and those for K ncreased during study, these differences were ot significant. The Na:K ratio also remained onstant. In all dogs, the 24-hr. urine volume nd Na excretion decreased significantly and K itput increased during aldosterone admin. No ffect of D-aldosterone on the handling of Na, and Cl by the small intestine could be emonstrated.

67 KINETIC RELATIONS OF THE Na-AMINO ACID INTERACTION AT THE MUCOSAL BORDER OF TESTINE. (E.)

Curran, P. F. (Harvard Med. h., Boston, Mass.), S. G. Schultz, R. A. Chez d R. E. Fuisz. J. Gen. Physiol. 50(5):1261-1286, 67.

udies on the relation between unidirectional uxes of Na and amino acids (3.3 mM alanine, 20 valine, 3.3 mM alanine, 20 mM leucine) across e mucosal border of rabbit ileum are reported. a constant Na conc. in mucosal bathing soln. asic Ringer), amino acid influx obeyed chaelis-Menten kinetics, allowing determination max. influx and K_t (apparent Michaelis nstant). Reduction in Na conc., using choline substitute cation, caused an increase in K_t r alanine but had no effect on max. alanine flux. A linear function of Na conc. was given $1/K_t$. Similar results were observed with valine d leucine, both of which competitively hibited alanine influx in the presence and sence of Na. A model for the transport system suggested which involves combination of Na d amino acid with a single carrier or site ading to penetration of both solutes. It edicts that alanine should cause an increase Na influx and that the ratio of (extra Na ux)/(alanine flux) should vary with Na conc. e observed relation agrees closely with the edicted values for Na conc. from 5-140 mM. e results support the hypothesis that interactions between Na and amino acid transport depend in part on a common entry mechanism at the mucosal border of the intestine.

6668 ALANINE AND SODIUM FLUXES ACROSS MUCOSAL BORDER OF RABBIT ILEUM. (E.)

Schultz, S. G. (Harvard Med. Sch., Boston, Mass.), P. F. Curran, R. A. Chez and R. E. Fuisz. J. Gen. Physiol. 50(5):1241-1260, 1967.

An *in vitro* study of the unidirectional influx of Na and L-alanine from mucosal soln. (modified Ringer) into epithelium of rabbit ileum is reported. Influx of alanine is approx. 2.2 μmoles/hr. cm^2 in the presence of 140 mM Na. The influx is inhibited if the NaCl in the mucosal soln. is replaced by choline-Cl, mannitol, KCl, Tris-Cl or LiCl. Despite the strong dependence of alanine influx on Na in the mucosal soln., it is uninfluenced by marked reduction in intracellular Na pools. Alanine influx is not dependent on intracellular alanine conc. Na influx was markedly inhibited by the presence of Li. It is suggested that transport of Na across the mucosal border cannot be attributed to simple diffusion, although the net flux across this surface is in the direction of the electrochemical potential difference.

6669 THE INFLUENCE OF 2-AMINOETHYLENISOTHIURONIUM-HYDROBROMIDE (A) ON ^{22}Na-TRANSPORT IN THE ISOLATED SMALL INTESTINE OF NORMAL AND IRRADIATED RATS. (Ger.)

Phan Van Duyet (Charles U., Prague), V. M. Nejtek and Z. Dienstbier. Strahlentherapie 132(3):448-453, 1967.

Five groups of white rats (200-220 g) were used in these tests: (1) Controls; (2) The direct action of the title compound (A) upon ^{22}Na-transport in the isolated small intestine of normal, nonirradiated rats, both inner and outer soln. contained 150 μg A/ml; (3) The action of A upon ^{22}Na-transport 15 min. after i.p. inj. of 150 μg/g body wt., nonirradiated rats; (4) ^{22}Na-transport 48 hr. after whole body X-irradiation (800 r); (5) ^{22}Na-transport 48 hr. after whole body irradiation (800 r). Each rat was inj. i.p. with 150 μg/g A 15 min. prior to irradiation; (6) ^{22}Na-transport, 48 hr. after inj. i.p. of 150 μg/g A, nonirradiated rats. Ten-cm long sections of jejunum were used from the rats in all 5 groups; the inner fluid consisted of 1 ml Krebs-Ringer soln. containing 2 mg glucose per intestinal segment with the ends ligated; the outer fluid had the same composition with the addition of 60 μc ^{22}Na; 12 such segments were incubated in 600 ml of the outer fluid at 37° for 60 min.; the outer fluid was oxygenated. After incubation 1 ml of soln. was removed from each segment; the segment was blotted with filter paper, then dried for 24 hr. at 105°C. The radioactivity of the soln. as well as the dried section of intestine was measured by a gamma scintillator. The transport of ^{22}Na in Group 2 was increased *in vitro* 6.7% over the controls and the incorporation of ^{22}Na decreased 9.92%. Group 3 had a 6.2% decrease in transport and 20.5% increase in incorporation. Group 4 had a 22.94% decreased transport and 18.4% increased incorporation. Group 5 transport was normal; incorporation was increased 26.8%. In Group 6 both transport and incorporation were normal. The effect of A upon the intestinal tissue itself is obscured in the intact animal where A acts upon both the circulatory and respiratory systems. A does not inhibit the increased incorporation of ^{22}Na due to irradiation. Transport and incorporation values had become normal 48 hr. after admin. of A.

6670 SMALL INTESTINAL GLUCOSE TRANSPORT. PROXIMAL-DISTAL KINETIC GRADIENTS. (E.) Rider, A. K. (Columbia U., New York City), H. P. Schedl, G. Nokes and S. Shining. *J. Gen. Physiol*. 50(5):1173-1182, 1967.

Proximal and distal segments of rat small intestine were perfused *in situ* at 2 different rates with isotonic soln. containing glucose at 25-600 mg/100 ml. Absorption was measured as rate of disappearance of glucose from lumen. Previous studies had not used intraluminal glucose conc. above and below blood glucose. Absorption was more rapid from the proximal segment. In both segments absorption was independent of perfusion rate or method of glucose analysis (^{14}C-counting or Somogyi method). This suggests that unidirectional flux out of the bowel is much greater than that into the bowel. Neither segment showed rate-limiting kinetics and Michaelis-Menten analysis could not be applied. The 2 segments gave different curves of absorption rate as a function of conc. At higher conc. absorption rate continued to increase much more rapidly in the proximal than in the distal segment. Presently accepted mechanisms of glucose transport are not capable of accounting for these results.

6671 INVESTIGATIONS ON THE INSULIN EFFECT ON THE INTESTINAL ABSORPTION OF GLUCOSE AND FRUCTOSE. (Ger.) Mehnert, H. (U. Munich, Germany), H. Förster and G. Haslbeck. *Diabetologia* 3(1):23-29, 1967.

Fasted, mature rats were inj. with a fast-acting insulin, or, for long-term insulin treatment, with a depot insulin s.c. Two methods were used to introduce the test soln. into the intestinal tract; in the first, 1.3 ml of soln. containing 10% polyvinylpyrrolidone and 30% or 50% sugar was introduced into the stomach by intubation. The animals were killed 15, 30, or 60 min. after the beginning of the test, the abdomen opened and the digestive tract ligated at the cardia, the pylorus and the ileocecal junction; the tract was then excised, cooled and washed; the contents of stomach and intestine were separately washed out with known quantities of ice-cold distilled water. In the second method, the rat under anesthesia was laparotomized and catheters tied into the upper duodenum and lower ileum; the abdomen was then closed and the small intestine perfused continuously with soln. warmed in a water bath to body temperature. This method permitted direct measurement of the absorptive capacity of the small intestine in the living rat. Through the use of 60 ml of the test soln. the conc. of the test substance in the intestinal lumen was only slightly changed during the test period. The polyvinylpyrrolidone (which is not absorbed) served as an index of the amount of water absorbed. After the admin. of the monosaccharides by stomach tube an accelerated absorption of glucose, but not of fructose, was seen under the action of insulin; the glucose absorption was more rapid however, only when larger amounts of glucose/unit time were offered to the intestinal surface; further investigation revealed that accelerated absorption of glucose after insulin inj. was caused by the more rapid emptying of the stomach; intestinal absorption of fructose is so much slower than absorption of glucose that faster gastric emptying has little effect on the rate of fructose uptake. When glucose and fructose were perfused through the intestine, no differences between insulin-treated animals and the controls were found. This observation refutes the idea that low blood sugar levels cause faster glucose absorption by increasing the conc. gradient between intestine and blood. When insulin was inj. i.v. 10 min. before the perfusion of the small intestine, there was a significant inhibition of absorption. The range of absorption was from 28.3% (1 U insulin) to 17.3% (80 U of insulin), whereas the av. absorption of controls receiving insulin-free inj. and no inj. was 35.5%. This inhibition of absorption in insulin-inj. animals may have been due to decreased metabolic rate caused by hypoglycemia. Pretreatment of animals with insulin for 1 wk. did not cause accelerated glucose absorption.

6672 EFFECT OF AMINO-ACIDS ON THE TRANSPORT OF BOVINE IMMUNE LACTOGLOBULIN ACROSS NEWBORN PIG INTESTINE. (E.) Smith, M. W. (Inst. Animal Physiol., Babraham, Cambridge, England) and A. E. Pierce. *Nature* (*London*) 213(5081):1150-1151, 1967.

Piglets removed from the sow immediately after birth were studied within 2 hr. of birth. The whole of the small intestine was divided into 10 segments of equal length and segments 6 and 7 were used. Everted sacs were formed from these segments and were partly filled with 0.3 ml of bicarbonate saline and incubated in bovine colostrum, dialyzed previously against bicarbonate saline for 2 hr. at 37°C. An amino acid was sometimes added to the bovine colostrum after dialysis in a conc. of 10

oles/liter. Transmural potentials were
corded during incubation; fluid transfer was
lculated at the end of incubation. Control
rosal transfers were: bovine immune lacto-
obulin, 61.6 μg/g/hr.; fluid, 0.5 ml/g/hr.;
ucose, 1.9 mg/g/hr. The control transmural
tential was 4.4 millivolts. L-Alanine did not
ve any effect. L-leucine inhibited protein trans-
rt more than 60%, fluid transport nearly 40%
d glucose nearly 70% with no effect on trans-
ral potential. The effect on protein trans-
rt may have been secondary to water and glucose
hibition. L-Methionine inhibited protein
ansport more than 40% without changing
ansmural potential or serosal transfer of
uid or glucose. None of these effects were
en with the D-isomers. The specificity of L-
thionine as an inhibitor of protein transport
plies a direct action on some part of the
otein-transferring mechanism; the absence of
fect with the D-isomer eliminates the
ssibility that the inhibitory action is
pendent on electrical charge carried by the
lecule.

73 ALANINE TRANSPORT ACROSS ISOLATED
RABBIT ILEUM. (E.) Field, M. (Beth
rael Hosp., Boston, Mass.), S. G. Schultz and
F. Curran. Biochim. Biophys. Acta 135(2):
5-243, 1967.

en both sides of isolated segments of ileum of
w England white rabbits (2.5-4.0 kg) were
thed in Ringer's soln. with 140 mM Na and 5
L-alanine, a net flux of L-alanine from
cosal to serosal soln. of 1.2 μmoles/hr. cm^2
s observed. The flux from mucosa to serosa
s 10 times that in the opposite direction.
t flux of L-alanine almost equaled the in-
ease in active Na flux caused by the addition
5 mM L-alanine to the serosal soln.
placement of Na with choline or addition of
$^{-4}$ M ouabain to serosal soln. in the presence
Na markedly inhibited net transport of L-
anine. In both cases this is due to a decrease
the flux from mucosa to serosa. Transport is
t significantly inhibited by addition of
abain to mucosal soln. alone. Net transport
D-alanine in the absence of a conc. difference
d accumulation of D-alanine to high conc. by
is tissue was observed. Addition of ouabain
replacement of Na with choline in the
cubation medium markedly inhibited the
cumulation.

74 EFFECT OF S-(1,2-trans-DICHLOROVINYL)-
L-CYSTEINE ON THE TRANSPORT OF AMINO
IDS AND GLUCOSE BY EVERTED SEGMENTS OF RAT
ALL INTESTINE. (E.) Chang, T. (Parke, Davis
Co., Ann Arbor, Mich.), J. Lewis and A. J.
azko. Biochim. Biophys. Acta 135(2):244-255,
67.

(1,2-trans-dichlorovinyl)-L-cysteine (DCVC)
ppressed active transport of glucose, glycine
and certain L-amino acids including alanine, valine, histidine, leucine and phenylalanine (everted sacs of small intestine of 180-240 g albino male Holtzman rats). The inhibition was proportional to the conc. of DCVC and was not readily reversed by washing. Passage of D-phenylalanine in both directions showed no marked changes in permeability of sacs in the presence of DCVC. The inhibition of uptake of L-phenylalanine by this tissue seemed to be a competitive process. At low conc. DCVC itself underwent active transport, with greatest transport in the mid-jejunum and least in the duodenum. Transport of DCVC was inhibited by absence of Na, anaerobiosis, dinitrophenol and low temperature.

6675 DISACCHARIDASE: LOCALIZATION IN
HAMSTER INTESTINE BRUSH BORDERS.
(E.) Johnson, C. F. (U. Chicago Sch. Med., Ill.).
Science 155(3770):1670-1672, 1967.

The brush borders were prepared from 15 cm of jejunum from 2 or 3 adult hamsters. Suspended in ethylenediaminetetraacetate the brush borders were digested with papain activated by cysteine and 30 mEq/liter of K at 37°C for 10 min. The mixture was cooled and centrifuged at 90,000 g for 90 min. The resulting pellet was prepared for electron microscope examination. The supernatant was further centifuged at 140,000 g for 5 hr. The sediment produced, as well as the supernatant, were prepared for examination. Phosphotungstic acid (2%) was used for negative staining. The specific activities of invertase and maltase were determined for all samples. The highest activity was in the 140,000 g sediment. It was found that digestion with activated papain removes knobs 60 Å in diameter from the plasma membrane. They were attached to the plasma membrane but were not an integral part of it. The activities of the disaccharidases, invertase and maltase were found to reside in the knobs and were not found with the plasma membrane. The author concludes that the knobs and enzyme activities are contained in the glycocalyx or fuzzy coat, external to the plasma membrane of the microvillus.

6676 EFFECT OF DIET UPON INTESTINAL
DISACCHARIDASES AND DISACCHARIDE
ABSORPTION. (E.) Deren, J. J. (State U. New
York, Brooklyn), S. A. Broitman and N. Zamcheck.
J. Clin. Invest. 46(2):186-195, 1967.

Feeding a carbohydrate-containing diet for 24 hr. to rats previously starved for 3 days led to a two-fold increase in total intestinal sucrase and sucrase-specific activity. Specific activity of maltase was similarly increased but lactase activity was unaffected. A diet containing sucrose resulted in a greater increase in sucrase than maltase activity, whereas the converse was true of a maltose-containing diet. Carbohydrate-free isocaloric diet increased total intestinal sucrase; sucrase-specific activity was unchanged. Adrenalectomized rats maintained on 1.0% salt intake had normal sucrase and maltase levels. Steroid admin. did not increase their activities. The response to sucrose feeding was similar in control and adrenalectomized rats indicating the absence of steroidal control on sucrase and maltase activity in adult animals. Sucrose hydrolysis by intact cells studied in the intestinal ring preparation was more rapid in animals fed sucrose. The increased enzyme levels in homogenates after dietary manipulation was reflected in the results of intestinal perfusion studies. Sucrose hydrolysis increased two-fold and fructose absorption four-fold in animals fed sucrose when compared to either fasted or casein-fed rats.

6677 RAT SMALL-INTESTINAL β-GALACTOSIDASES. INFLUENCE OF pH ON THE HYDROLYSIS OF DIFFERENT SUBSTRATES. (E.) Dahlqvist, A. (U. Lund, Sweden) and N. G. Asp. Biochem. J. 103(1): 86-89, 1967.

The influence of pH and type of buffer on the hydrolysis of lactose and 4 hetero-β-galactosides (phenyl-β-galactoside, 6-bromo-2-naphthyl-β-galactoside, o-nitrophenyl-β-galactoside and p-nitrophenyl-β-galactoside) by homogenates of adult albino rat small-intestinal mucosa was investigated using the following buffers: glycine-HCl at pH 1.5-3.5, sodium citrate or sodium acetate at pH 3.0-6.5, sodium phosphate at pH 6.0-8.0, and glycine-NaOH at pH 8.0-9.0. At least 2β-galactosidases were found to be present in the homogenates, one with optimum pH 3-4 and another with optimum pH 5-6. The enzyme with the lower pH optimum was mainly a heterogalactoside, and it hydrolyzed lactose slowly; the second enzyme was chiefly a disaccharidase, since it hydrolyzed lactose much more quickly than the heterogalactosides. Citrate had an inhibitory effect on the activity of 6-bromo-2-naphthyl β-galactosidase at pH 3-4; however, citrate did not influence 6-bromo-2-napthyl β-galactosidase activity at pH 5-6 or the hydrolysis of the other substrates at any pH.

6678 INTESTINAL DISACCHARIDASE ACTIVITY IN PREMATURE NEONATES AND NEONATES BORN AT TERM. (It.) Apollonio, T. (U. Milan, Italy), O. Palumbo-Vargas and G. Cevini. Minerva Pediat. 18(37):2183-2185, 1966.

Preparations of intestine were derived at autopsy from 10 premature infants and 2 neonates born at term. Preparations were also derived by biopsy from 2 adult subjects. For these 3 groups, mean cellobiase activity in terms of U/g mucosa was 2.6 (range = 0.4-8.8), 3.3 (range = 3.0-3.6) and 2.9 (range = 2.8-3.0), resp. Comparable tabulations for trehalase activity were 4.0 (range = 0.5-15.4), 5.2 (range = 2.1-8.3) and 6.4 (range = 3.3-9.5), resp.; for palatinase activity, they were 0.5 (0.07-1.10), 2.0 (1.80-2.30) and 0.9 (0.60-1.20) resp. There were no statistically significant differences between the 3 groups, as concerned the mean values found for maltase, lactase or sucrase activity; in all 3 cases, the range was extremely variable. Note is made that these findings in human subjects are strongly at variance with reported experimental findings in rats and other animals.

6679 EFFECT OF E.D.T.A. ON THE INTESTINAL ABSORPTION. (It.) Giorgi, G. (U. Camerino, Italy) and G. Segre. Boll. Soc. Ital. Biol. Sper. 42(20):1438-1440, 1966.

Adult rabbits (both sexes 1.5-2.0 kg) received para-aminohippuric acid in the form of its Na salt (50 mg/kg, i.v.) followed by determinations of serum conc. of the same substance at interval between 5-90 min. Each animal then underwent laparotomy and received 1 g/kg intraduodenally, with a further determination of serum conc. made at 210 min. As compared to controls receiving para-aminohippuric acid alone, intraduodenally, animals receiving ethylenediaminotetraacetic acid 100, 250 or 500 mg at the same time and by the same route, showed significantly increased intestinal absorption of para-aminohippuric acid. The effect was directl dose-related.

6680 PITUITARY-ADRENAL SUPPRESSION FOLLOWING INTRARECTAL ADMINISTRATION OF DEXAMETHASONE-21-PHOSPHATE. (E.) Sparberg, M. (Wilford Hall USAF Hosp., Lackland AFB, Tex.), R. Jensen, S. C. Beering and I. Shannon. Gastroenterology 52(3):519-520, 1967.

Basal blood samples were collected in the morning in 2 groups of healthy men (17-22 yr., in military service after 8 wk. basic training). A p.o. dose of 1 mg dexamethasone or dexamethaso 21-phosphate in 45 ml water as a retention enema was admin. at that time and samples collected again after 7 hr. Sera were analyzed for free (unconjugated) 17-hydroxycorticosteroid content. The control values for serum 17-hydroxycorticosteroids agreed with the accepted normal diurnal pattern. A significant decrease was observed with dexamethasone in 7 hr. This indicates that pituitary-adrenal suppression occurs following admin. of a small dose of dexamethasone in the morning as well as at night. A similar and significant fall was observed in the dexamethasone-21-phosphate group. Therefore, therapeutic amounts of intrarectal corticosteroi may produce significant pituitary-adrenal suppression regardless of time of admin. It is suggested that these short-term results may be applicable to long-term therapy, and a suggested alternative might be the use of the less effective, nonabsorbable preparation or the

:ermittent intrarectal admin. of soluble
rticosteroids.

31 METABOLISM AND RECONJUGATION *IN VIVO*
OF (7α-^{3}H)ANDROSTENDIONE, (7α-^{3}H)-
)ROSTENOLONE, AND (7α-^{3}H)ANDROSTENOLONE
LFATE IN THE WALL OF THE HUMAN INTESTINE.
er.) Knapstein, P. (U. Mainz, Germany), L.
eiber, F. Wendlberger and G. W. Oertel.
ppe Seyler. *Z*. *Physiol*. *Chem*. 348(4):401-404,
57.

e first patient received (7α-^{3}H)androstendione
,17) with 7,000,000 ipm and (7α-^{3}H)-
drostenolone with 13,500,000 ipm in the lumen
the upper duodenum; in the following 30 min.
mples of blood were withdrawn from the
odenal vein. The second patient received
:-^{3}H)androstenolone sulfate with 70,200,000
n in the lumen of the upper ileum; from
-120 min. later blood samples were withdrawn
om the iliac vein. The third subject received
inj. of (7α-^{3}H)androstenolone with
,140,000 ipm in the upper mesenteric artery;
ood was immediately drawn from the correspond-
g mesenteric vein. The fourth subject
ceived (7α-^{3}H)androstenolone sulfate with
,800,000 ipm in the same manner as the third
oject; collection of blood was also the same.
tal C$_{19}$-steroids were extracted from the blood
mples and separated into free steroids,
eroid sulfatides, steroid sulfates, and
eroid glucuronides, and metabolic products
in subject 1, 3 in subject 2, and 1 in
ojects 3 and 4). In the first patient 79.5%
the total free radioactive androstendione and
drostenolone were conjugated to sulfate and to
ucuronic acid in the intestinal wall and 14%
tabolized. It was impossible to know which
mpound gave rise to particular metabolites.
is test, however, gave rise to more metabolites
th greater conc. than the other 3. These
oducts, some in traces only, were (a) "polar
g steroids", (b) androstenolone, (c) 5,β-
drostanolone, (d) androsterone, (e) androstendi-
e, (f) estriol, (g) estradiol, and (h)
trone. Androstendione and androstenolone, the
iginal steroids, are also classed as products.
dioactive androstenolone sulfate introduced
to the intestinal lumen of the second patient
s recovered in the venous blood as 1) 80.3%
eroid sulfatide; 2) 14.4% as steroid sulfate;
4.9% as free steroid; and 4) 0.4% as steroid
ucuronide. Among the metabolites isolated
om sulfatide and sulfate conjugates, 98.1% of
e radioactivity was from androstenolone, and
ly 1.7% from 5β-androstanolone, and 0.13%
om androsterone. Although the conversion to
lfatide from sulfate was massive, there was
ry little metabolism of the steroid itself.
e inj. of free (7α-^{3}H)androstenolone (third
tient), after a single passage through the
ood vessels in the wall of the intestine,
sulted in 93.7% remaining unchanged, 5.6%
njugated to sulfate and 0.7% bound to
ucuronic acid. In the fourth subject 72.9%
of the androstenolone sulfate was converted to sulfatide; no metabolism of the steroid was demonstrable.

6682 AMMONIA MOVEMENT IN THE SMALL INTESTINE: PREFERENTIAL TRANSPORT BY THE ILEUM. (E.) Mossberg, S. M. (33 Quaker Ridge Rd., New Rochelle, N. Y.) and G. Ross. *J*. *Clin*. *Invest*. 46(4):490-498, 1967.

Isolated, surviving sacs of everted small intestine were used to characterize ammonia transport in the golden hamster. Jejunal and ileal sacs incubated aerobically in ammonia-free test soln. liberated the same quantity of ammonia as did sacs that were filled and immediately emptied of their contents, indicating no significant evolution of metabolic ammonia. Under aerobic conditions, ileal sacs transferred a soln. of high ammonia content from the mucosal surface to the serosal surface against a conc. gradient. This transport was not glucose dependent and exhibited first-order Michaelis-Menten kinetics. Inhibition of absorption occurred with anaerobiosis, 2,4-dinitrophenol, and NaCN. In jejunal segments ammonia was not transported against an adverse chemical gradient. Ileal ammonia absorption was accompanied by bicarbonate secretion and acidification of the serosal soln. Both bicarbonate movement and pH gradients were abolished by inhibitors of ammonia transport. In the jejunum, the absence of ammonia movement occurred in association with minimal bicarbonate secretion and no appreciable change in serosal pH. Despite creation of H gradients augmenting or retarding ammonia absorption by nonionic diffusion, ammonia movement was unaffected, acidification of serosal contents did not augment ammonia absorption and alkalinization caused no inhibition. In the absence of bicarbonate ion, ammonia transport did not occur. It is suggested that ammonia is absorbed in the ileum by active ionic transport.

6683 THE INTRACELLULAR DISTRIBUTION OF [1-^{3}H]CHOLECALCIFEROL IN THE INTESTINE OF VITAMIN D-DEFICIENT AND -SUPPLEMENTED RATS. (E.) Wilson, P. W. (U. Cambridge, England), D. E. M. Lawson and E. Kodicek. *Biochem*. *J*. 103(1):165-171, 1967.

Vitamin D-deficient and -supplemented male and female piebald weanling rats were admin. [1-^{3}H]-cholecalciferol (2.5 or 500 µg/rat), and the intracellular distribution of the vitamin in the intestinal mucosa was studied. Cholecalciferol conc. was highest in a fraction consisting of brush borders and nuclei. The microsomal fraction contained a higher conc. of cholecalciferol than the mitochondrial fraction in deficient rats, irrespective of the dose; however, in vitamin D-supplemented rats, the conc. was the same in the 2 fractions. There was appreciable metabolism of cholecalciferol in supplemented rats only, and the metabolites were found predominantly in the mitochondrial fraction. Cholecalciferol was bound more tightly to the microsomal fraction than to the mitochondrial fraction. *In vitro* experiments revealed that all of the intracellular particles combined with the vitamin when dissolved in ethanol or bound to albumin. Nevertheless, such an uptake did not account for the high conc. of radioactivity found *in vivo* in the fraction containing nuclei and brush border, nor for the tightly bound vitamin in the microsomal fraction.

6684 FLUID TRANSFER IN THE EVERTED HUMAN GALLBLADDER. (E.) Onstad, G. R., (Mayo Clin., Rochester, Minn.) L. J. Schoenfield and J. A. Higgins. *J*. *Clin*. *Invest*. 46(4): 606-614, 1967.

The rates of fluid transfer across human gallbladders (47, all of which contained gallstones), obtained at cholecystectomy from patients having chronic cholecystitis with cholelithiasis, were determined by measurement of wt. changes of everted preparations under controlled conditions. The modified Ringer's bicarbonate bathing soln. contained (in mmoles/liter) Na 150, K 4.5, Ca 2.5, Mg 0.5, Cl 130, HCO_3 25, HPO_4 1.2, SO_4 0.5 and dextrose 10. Of 47 gallbladders, 27 gained wt. (av. gain was 1.00 g/hr. or 13% of the initial intraluminal vol./hr.) and 20 lost wt. (at a mean linear rate of 7%/hr.). Active transport of fluid from the mucosal to serosal surface was indicated, since wt. gain occurred with the same soln. on both sides of the membrane and against hydrostatic, osmotic and potential differences. The fluid transferred was isotonic to the bathing soln., with respect to Na. Metabolic inhibitors (NaCN and iodoacetic acid, at 1×10^{-3} mole/liter, and dinitrophenol, at 1×10^{-4} mole/liter) and temperature extremes inhibited wt. gain. In 10 preparations, the av. potential difference across the gallbladder wall after 30-40 min. of wt. gain was 6 millivolts, with the mucosal surface negative to the serosal surface. Muscle contractions in this *in vitro* preparation were related to the rates and direction of fluid movement. Cholecystokinin (0.50 dog U/ml, with a range of 0.23-2.94) increased muscle activity and caused wt. loss in preparations that previously had gained wt. Norepinephrine (0.052 mg/ml, with a range of 0.008-0.169) caused wt. gain or increased wt. gain in all preparations tested. The direction of net fluid movement in the isolated everted human gallbladder was determined by the opposing forces of active mucosal transport and a filtration pressure generated by muscle contractions. Of the gallbladders examined, 9 of 11 that gained wt. and 4 of 19 that lost wt. were normal histologically. Chronic inflammation was present only in the submucosal and muscle layers. Mucosa from 7 gallbladders, obtained after 50-150 min. of wt. gain, was examined electron-microscopically and showed ultrastructural detail similar to that of the normal human gallbladder.

6685 KINETIC FORMULAS OF ABSORPTION IN REFERENCE TO INTESTINAL BLOOD FLOW. (Ger.) Winne, D. (U. Tubingen, Germany) and H. Ochsenfahrt. *J*. *Theor*. *Biol*. 14(3):293-315, 1967.

The kinetics of absorption (based upon solubilitie conc. of solute and solvent, diffusion, osmotic pressure and permeabilities) is considered step by step from the most simple case, a 2-compartment model where the compartments are separated by a semipermeable membrane, or a layer of cells or multiple layers which, in this sense, act as a single membrane; in which case 1 compartment can be considered the lumen of the intestine (intestinal fluid) and the other compartment the vascular lumen (blood) with tissue layers (membrane) separating the compartments. Then the movement of a single species of molecule or ion from 1 side of the membrane to the other, as the influx, I, from the intestinal fluid into the blood plasma is equal to $k_1 \times F_D \times C_D$ where k_1 is the permeability constant, F_D is the conc. in the membrane, and C_D is the conc. in the intestinal fluid. $\bar{I} = K_1 \times F_D \times C_D$ is opposed by the same set of factors (of different magnitudes) operating on the other side of the membrane. The authors continue to 3-compartment models such as blood, interstitial fluid, and intestinal fluid. They then introduce special cases, as zero conc. of a molecular species in 1 compartment, radioactive markers, both solute and solvent, and time-dependent conc. of solutes. The treatment is simple, straightforward and clear. Some explanations may be oversimplified; however, the formulas are true.

6696 THE MAXIMAL HISTALOG TEST OF GASTRIC SECRETION. A COMPARISON WITH THE HISTAMINE INFUSION TEST IN MAN. (E.) Johnston, D. (Roy. Infirm., Sheffield, England) and D. W. Robinson. Brit. J. Surg. 54(3):207-210, 1967.

Subjects were 17 men (24-67 yr., av. 40) with duodenal ulcer (12), gastric ulcer (2), dyspepsia without X-ray evidence of a gastrointestinal abnormality (3). Histamine (with 36% histamine base) was admin. i.v. (0.04 mg/kg/hr.) by a slow inj. pump for 2 hr. Mepyramine maleate was inj. (50 mg; 100 mg in those over 70 kg) 5 min. before infusion. Betazole was inj. s.c. into the flexor surface of the forearm (2 mg/kg). No antihistamine was given. Each subject underwent both tests, with minimal interval of 1 day between tests, and tests given in random order. Stomach contents of fasting subjects were aspirated by nasogastric suction and discarded, and continuous suction with air-forced tube patency was maintained. In all, the stomach was emptied completely before drug admin., and specimens were taken at 15-min. intervals over 2 hr. Sample vol. were measured and acid conc. determined by titration with NaOH. Max. acid outputs were nearly identical after both tests. Mean difference between output after histamine and that after betazole was 0.056 mEq/15 min. The peak 30-min. ('max. acid output' was acid output in 2 consecutive 15-min. periods giving highest reading) occurred in the last 45 min. in 12 of the histamine tests, but at 45-75 min. in most (6) of the betazole. The peak was reached earlier in the betazole test, but scatter was greater. Spontaneous secretion was 15.5% of the peak secretion in response to histamine in 12 tests. There was no significant difference between conc. and outputs of pepsin in response to the 2 tests. Side effects were similar and mild, but betazole showed a slight superiority: 11 of 17 had no preference; 5 preferred betazole; 1 histamine Subjects were more tired with histamine than with betazole. Severe reactions were seen in 5% of the 140 histamine tests. It is concluded that, until gastrin becomes freely available, betazole (2 mg/kg) provides the best means of eliciting 'max.' gastric secretion.

6697 A CLINICAL EVALUATION OF THE MAXIMAL HISTALOG TEST. (E.) Goldenberg, J. (U. Tennessee Coll. Med., Memphis), A. J. Cummins and M. L. Gompertz. Amer. J. Dig. Dis. 12(5): 468-474, 1967.

Subjects were 131 patients (13-80 yr.) with: no demonstrable gastrointestinal disease (= controls, 42); duodenal ulcer (48); gastric ulcer (11); gastric carcinoma (3); after subtotal gastrectomy with or without vagotomy (9); pernicious anemia (18). Gastric analyses were performed in each after an overnight fast. Residual gastric juice was emptied, a nasogastric tube was connected to continuous suction and basal aspiration was conducted for two 30-min. samples, with forced-air tube patency. The tube was positioned fluoroscopically in 67 of 131. In 30, 50 mg diphenhydramine was given i.m. 30 min. after beginning of test. After 1 hr., betazole was inj. (2 mg/kg, never more than 200 mg) s.c. Four more 30-min. gastric secretion samples were obtained. Vol. and pH of each sample was measured and acid conc. determined by titration with NaOH. Acid output (mEq/hr.) was expressed as the combination of values of 2 consecutive 30-min. samples (0-60, 30-90, 60-120 min.) afte betazole inj. Due to range of doses and data, the variance ratio was used. Of 48 with duodena ulcer, 22 had the tube positioned fluoroscopica acid secretion in the highest output hr. (30-90 min.) was 31.6 mEq/hr. in these; 22.6 mEq/hr. in those not fluoroscopically placed. The decrease in gastric juice was statistically significant, and fluoroscopic positioning is considered necessary. Fourteen controls were 'positioned'. Whereas the highest mean level of secretion in the control group occurred at 60-120 min., that in the duodenal ulcer patient at 30-90 min, after stimulation. Mean differen in rates was significant at 0-60 min., slightly so at 30-90 min. and not at all at 60-120 min. Fluoroscopic positioning was performed in 3 wit gastric ulcer, 9 with gastric resection, 18 wit pernicious anemia. Ulcer patients had a normal secretory pattern; the 9 resections had av. outputs below control values; all 18 with pernicious anemia were achlorhydric with a gast juice pH of 6.9 or higher. Side reactions included tachycardia, headache, weakness and mild flushing. Large amounts of blood were recovere in the stomach of 14 subjects after drug admin. In 3 (54, 77, 82 yr.) vasomotor collapse occurred 30 min. after admin. of betazole, but all responded to s.c. admin. of 0.5 ml epinephrine (1:1000).

6698 DETERMINATION OF THE DOSE OF HISTAMIN CAUSING MAXIMAL GASTRIC ACID SECRETIO IN THE PYLORUS-LIGATED RAT. (E.) Thompson, J. (UCLA Sch. Med., Los Angeles, Calif.) and Y. H. Lee. Amer. J. Dig. Dis. 12(5):449-455, 1967.

Rats were weighed after a 24-hr. fast. Under ether, an upper abdominal incision was made, the pylorus ligated, gastric lavage was perform with introduction and immediate withdrawal of 4 ml of warm normal saline. Rats were used between early and midmorning on the day of stud After recovery from ether, rats were randomly divided into 10 groups and histamine (1 mg base/2.76 mg) was admin. s.c. in doses of 0 (controls), 3.125, 6.25, 12.5, 25.0, 25.0, 35.3 50.0, 70.7, 100, and 200 mg/kg. Rats received no antihistamine. Controls received s.c. inj. of normal saline. Neither death nor histamine intoxication was observed during experiments. Two hr. after ligation, rats were rapidly anesthetized and the stomach removed after

sophageal ligation. All were macroscopically
ormal. Stomachs were trimmed of mesentery,
ashed, blotted dry. The greater curvature was
ncised, gastric juice collected. After centri-
ugation (5000 g for 10 min.), the vol. of
upernatant and solids was measured. After selec-
ion, each group contained 10-12 rats. Total
cidity of the sample was measured by titration
ith NaOH. Acid output (μEq/kg/2 hr.) at the
bove histamine doses was: 70, 85, 80, 90, 180,
15, 290, 190, 170, 150. The peak response (290
Eq/kg/2 hr. at 50 mg/kg histamine) was highly
ignificant. Gastric secretory vol. and total
cidity varied linearly. Gastric juice vol.
aralleled acid output. There was a significant
ifference between control values for gastric
uice vol. and gastric juice vol./100 g on the
ne hand, and these values after 50 mg/kg hista-
ine. Doses of histamine larger than the peak
0 mg/kg) depressed both acid output and gastric
uice vol. It is concluded that histamine is a
owerful stimulant of rat gastric acid secretion
nd that max. acid secretion occurs in pylorus-
gated rats with histamine at 50 mg/kg.

99 EFFECTS OF *IN VITRO* NEUTRALIZATION ON
THE COMPOSITION OF THE NONDIALYZABLE
OMPONENTS OF HUMAN GASTRIC JUICE. (E.) Welsh,
D. (U. Oklahoma Med. Ctr., Oklahoma City),
D. Wallace, A. Walker and L. Russell. *Amer.*
Dig. Dis. 12(4):389-395, 1967.

astric content was collected from 32 fasting
atients through a nasogastric tube with continuous
uction for 30 min. following inj. of histamine
).04 mg/kg) and chlorpheniramine (15 mg). Each
ollection was divided into 2 equal vol. One sample
as neutralized with 0.1 *N* NaOH to pH 7.0 The
amples were separately dialyzed in cellophane
ags against 9 changes of distilled water for 3
ays in the cold, following which they were
yophilized. Wt., hexose and nitrogen content,
roteolytic enzyme activity and B_{12}-binding
apacity were determined. When the paired samples
ere compared, *in vitro* neutralization and dialysis
educed the conc. of the proteolytic enzyme activity
nd increased the conc. of hexoses and B_{12}-binding
aterials. *In vitro* neutralization and dialysis
educed the wt. of the samples and the total
roteolytic enzyme activity while the total B12-
inding material was increased. Nitrogen conc.
as reduced. One patient received a continuous
istamine infusion (0.7 mg/hr.) for 7 hr.; secre-
ions were collected half-hourly. The samples
ere divided and 1 sample neutralized. In each
)-min collection the nitrogen content of the
eutralized sample was less and the other values
ere similar to the 32 individual cases. It is
oncluded that experiments utilizing neutralization
nd dialysis of gastric juice must be interpreted
ith caution when the results are being related
o secretion.

00 THE EFFECTS OF SECRETIN, PANCREOZYMIN,
AND GASTRIN ON INSULIN AND GLUCAGON
SECRETION IN ANESTHETIZED DOGS. (E.) Unger, R. H. (U. Texas Southwest. Med. Sch., Dallas), H. Ketterer, J. Dupré and A. M. Eisentraut. *J. Clin. Invest.* 46(4):630-645, 1967.

Anesthetized mongrel dogs were prepared for study by placement of an indwelling needle in the pancreaticoduodenal vein in the direction of venous flow. The femoral vein and femoral artery were catheterized. A catheter was inserted into a mesenteric vein and saline infused intraportally (2 ml/min.), throughout the experiment. Blood samples were obtained before and after intraportal inj. or infusion of secretin, pancreozymin-cholecystokinin, and of a crude gastrin-containing extract of hog antrum. All these preparations increased the insulin conc. in the pancreaticoduodenal plasma, with a peak effect occurring 1 min. after inj. Only pancreozymin raised pancreaticoduodenal venous glucagon, reaching a peak 3 min. after inj.; hyperglycemia occurred soon after. Intraportal infusion of secretin and pancreozymin for 20 min. produced qualitatively similar, but sustained, effects. The beta-cytotropic effect of secretin was abolished by infusion of epinephrine. These results could not be attributed to contamination of the preparations. It is concluded that secretin, pancreozymin and, probably, gastrin have insulin-releasing activity; pancreozymin, in addition, has glucagon-releasing activity. These findings suggest that there is a chain of beta-cytotropic hormones in the gastrointestinal tract capable of augmenting insulin secretion as required for disposal of substrate loads, preventing high substrate conc. that would otherwise follow ingestion of large meals if the insular response were entirely a function of arterial substrate conc.

6701 STUDIES ON ANTIBODY TO INTRINSIC FACTOR. (E.) Schade, S. G. (U. Wisconsin, Madison), J. Abels and R. F. Schilling. *J. Clin. Invest.* 46(4):615-620, 1967.

Sera from a group of 79 patients with pernicious anemia were studied for the presence of antibody to intrinsic factor. Three different tests were used: charcoal absorption technic, electrophoretic retention test, and coprecipitation tests. Two general types of antibody activity were found, and it was possible to distinguish 3 groups of pernicious anemia sera on the basis of their content of these types. Type I antibody blocked the binding of radioactive B_{12} to intrinsic factor when added to intrinsic factor before the B_{12}; it was not detected on intrinsic factor when added after B_{12}. This antibody blocked intrinsic factor-mediated B_{12} absorption *in vivo* when mixed in the sequence, intrinsic factor + antibody I + B_{12}. Type II antibody reacted with intrinsic factor when B_{12} was attached. This antibody prevented absorption of B_{12} from intrinsic factor in pernicious anemia patients when mixed in the sequence, intrinsic factor + B_{12} + antibody II, and was thereby distinguished from antibody I.

6702 THE PANCREATIC SECRETORY RESPONSE TO TOPICAL ANESTHETIC BLOCK OF THE SMALL BOWEL. (E.) Slayback, J. B. (Loma Linda Sch. Med., Calif.), E. M. Swena, J. E. Thomas and L. L. Smith. Surgery 61(4):591-595, 1967.

Adult mongrel dogs were prepared for study by placing a Thomas fistula into the duodenum opposite the major pancreatic duct, the accessory duct being ligated. A Thiry-Vella loop (20 cm) was made and a second Thomas fistula placed in the most dependent part of the stomach. During study, a glass cannula was inserted into the main pancreatic duct to allow collection of secretions, and the Thiry-Vella loop perfused by means of a Foley catheter, placed in the proximal end of the loop. HCl (20 ml of 0.075 N) was inj. into the loop followed by a 30-min. perfusion of the same soln. at a rate of 1.5 ml/min. The intestinal loop was then perfused with 0.4% oxethazaine soln. for 60 min. followed by restimulation with HCl. Collections of pancreatic juice were made throughout. The same protocol was followed using 5% Bactoprotone soln. instead of HCl soln. Topical anesthesia with oxethazaine followed by HCl stimulation caused an 86% decrease in pancreatic secretory vol., 93% reduction in amylase output, and a 94.5% decrease in lipase. Oxethazaine followed by Bactoprotone stimulation decreased secretors vol. 75%, amylase output 91% and lipase output 91%. The authors conclude that these findings are consistent with the presence of a local neural mechanism controlling the release of secretin and pancreozymin from the small intestine.

6703 RESPONSE OF THE ISOLATED DOGFISH GASTRIC MUCOSA TO HISTAMINE. (E.) Hogben, C. A. M. (Mount Desert Island Biol. Lab., Salisbury Cove, Maine). Proc. Soc. Exp. Biol. Med. 124(3):890-893, 1967.

Dogfish were caught and immediately used for experiment. The gastric mucosa was separated as a flat sheet and mounted in a plastic chamber, allowing both surfaces to be bathed with appropriate soln. The isolated gastric mucosa spontaneously secreted acid at a slow rate of 1-2 µEq cm^{-2}/hr.$^{-1}$. Histamine (200 µM) and carbachol (10 µM) increased secretory rates by 100-150%. The highest conc. of porcine gastrin used, 0.05 µM, did not elicit a marked response although this conc. was found to be adequate for isolated bullfrog mucosa. Peak secretory response occurred approx. 120 min. after the addition of a drug. The histamine content of the gastric mucosa of 2 dogfish was found to be 2.5 and 8.7 µg/g, similar to values reported for bullfrog mucosa. It is suggested that the relative insensitivity of the dogfish mucosa to hog gastrin can be explained by the relative insensitivity to extracellular histamine, but it is more likely due to species differentiation of the polypeptide gastrin, assuming that a gastrin hormone is liberated by the antrum of the elasmobranch.

6704 THE EFFECT OF PROLONGED WITHDRAWAL OF ENDOGENOUS STIMULI TO GASTRIC SECRETI (E.) Little, J. M. (Western Infirm., Glasgow, Scotland), S. P. Master, B. S. Bedi and I. E. Gillespie. Brit. J. Surg. 54(3):225-228, 1967.

Four dogs received a histologically-confirmed antrectomy with gastrointestinal continuity restored by a gastroduodenostomy. A small Heidenhain pouch was made and a gastric fistula cannula inserted into the most dependent part of the main gastric remnant. Measurement from the pouch should reflect effects of removing both vagal and gastrin backgrounds; measurement from fistula, removal of gastrin background alone, since vagal supply of main gastric remnant was intact. Responses of pouches to standard meat meal were determined after 1 mo. Duplicate histamine and gastrin dose-response curves were plotted from fistula and pouch, using continuous i.v. infusion. Histamine was used in doses of 0.5-16 mg/hr., gastrin (a synt ic pentapeptide gastrin-like substance I.C.I. 50,123) in doses of 0.5-8 µg/hr. Responses to methacholine (1 mg/hr.) were also plotted. Pouch and fistula secretions were collected continuously and acid output was determined eve 15 min. by measurement of vol. and of conc. by titration with NaOH. Tests were repeated after 4 mo. Two of the 4 showed no measurable acid response to the meal in either the early or lat tests. Acid responses were small (0-0.153, 0-0.039 mEq/hr.) in the other 2. When acid secretion did occur, it began after 2 hr. and probably represented the intestinal phase of gastric stimulation. In 3 dogs the main stomac remnant showed an overall reduction in height of curve; in the fourth a shift to the right and reduction in peak response. Av. peak response was reduced by approx. 30%, but the reduction was not statistically significant. Pouch changes were slight in 2, moderate in 2. Pooled curves showed a moderate overall reducti of the same magnitude as above, also not signif cant. With artificial gastrin, both fistulae and pouches showed a pronounced reduction in individual and pooled curves. Av. reduction wa 80% and was significant. With combined infusio of gastrin (8 µg/hr.) and methacholine (1 mg/hr the main stomach response was the same as with gastrin alone. Fistulae were constant with methacholine, pouches showing consistent and significant reductions in secretion. The resul suggest a biochemical disuse atrophy rather tha cellular atrophy.

6705 EXOCRINE PANCREAS ADAPTATION TO DIET IN VAGOTOMIZED RATS. (E.) Morisset, J. (U. Sherbrooke, Quebec, Canada) and J. Dunni Rev. Canad. Biol. 26(1):11-16, 1967.

When 200 g male Wistar rats were fed a high-protein diet, a decrease in amylase content and an increase in proteolytic enzyme content of their pancreas was observed. On a carbohydrate rich diet just the opposite was found. Adaptat

enzyme synthesis was not prevented by vagotomy,
pancreas of vagotomized rats exhibited higher
zyme activities than those of normals. Results
reported on amylase and chymotrypsin, and on
corporation of orotic-6-^{14}C acid into pancreas
, during fasting and at intervals after a meal.
zyme content was consistently higher in
gotomized rats than in normals. In the vagoto-
ed rats, beginning of active extrusion of
zyme material from the pancreas after the meal
delayed about 2 hr., but the quantity ex-
ted and the duration of excretion and of zymogen
ck reconstitution were the same in vagotomized
normal rats. In the normals, rate of RNA
rnover increases when extrusion of pancreatic
yme material begins and returns to baseline
n zymogen stocks are replenished.

6 EFFECT OF BILATERAL ADRENALECTOMY ON
GASTRIC ACID AND PEPSIN SECRETION FROM
TRIC FISTULAS AND HEIDENHAIN POUCHES IN DOGS.
) Cooke, A. R. (VA Ctr., Los Angeles, Calif.),
L. Nahrwold and M. I. Grossman. Gastroenterology
3):488-493, 1967.

ally-innervated gastric fistulae were con-
ucted in 2 dogs; gastric fistulae and vagally-
ervated Heidenhain pouches in 2 others; dogs
ted for 3 wk. Dogs were fasted for 18 hr.
ore tests and a hind leg vein was catheterized
permit i.v. infusion of 0.15 M NaCl by
istaltic pump (29 ml/hr.). Gastric juice was
lected from fistulae and pouch for two 15-min.
iods to obtain basal secretion levels. Gastrin
histamine was then added to saline, with
e doubled every hr. Gastrin juice was collected
ry 15 min., and vol. and conc. were measured,
was pepsin activity. After control studies
h dog was adrenalectomized and maintained on
l (4 g daily) and deoxycorticosterone acetate
5 mg i.m. every other day), and hydration was
ntained. Studies began on the third day.
er this regimen, the Heidenhain pouch animals
eived an i.v. infusion of hydrocortisone
0 mg) immediately, received 25 mg hydro-
tisone i.m. every day after this and were
tudied. One dog with fistula was tested for
effect of a continuous infusion of a high
e of histamine (6 mg/hr.) on blood pressure.
max. acid output in response to histamine
gastrin was not significantly different.
max. acid output with gastrin after
enalectomy was 49% and 42% of control values,
h histamine 39% and 49%. In control studies,
. acid output in response to histamine equaled
trin from fistula dog but was greater than
trin from the Heidenhain pouch dogs. After
enalectomy, the value from the fistula
mals decreased in response to histamine and
trin, but only to histamine from the pouch
s while that from the pouch dogs due to
trin stimulation was unaffected. Decrease in
retion in both preparations appeared by day
nd was well established by day 10, remaining
stant at a reduced value. There was no differ-
e in time course between dogs with both
preparations. After adrenalectomy, pepsin output was not significantly different from controls. Hydrocortisone restored acid secretion to normals. Normal dogs tolerated the highest histamine dose; adrenalectomized dogs collapsed due to severe hypotension.

6707 HYPERSECRETION OF GASTRIC ACID FOLLOWING PORTACAVAL SHUNT IN THE DOG. (CONTINUATION AND CONCLUSION.) (Fr.) Hubens, A. (U. Brussels, Belgium). Acta Gastroent. Belg. 30(1):7-55, 1967.

Following creation of portacaval shunt in dogs bearing Heidenhain pouches and weighing 15-20 kg at the start of the experiment, the 24-hr. secretion of gastric acid reached 3.5-7.0 times the initial level, with 3 of 4 animals showing a significant increase in the amount of free acid present while fasting. Postprandial acid response was also increased significantly. Acid response to s.c. inj. of submax. doses of histamine was 2.4-3.7 times preshunt levels; to s.c. inj. of 20 μg gastrin or 1 mg bethanechol chloride, it was 2.5-3.7 and 2.6-4.0 times preshunt levels, resp. However, the increase of acid response to histamine, when inj. s.c. into a hind paw, was only 19-45% as great as the response to inj. into a front paw, a phenomenon not paralleled in studies with gastrin or bethanechol chloride. It is suggested that these phenomena, like others reported previously, could be explained by a postshunt increase of the number of parietal cells, by an increase of the serum level of a hypothetical intestinal hormone with gastric acid secretory activity, or by an increase of cholinergic activity in the peripheral circulation in response to hypothetical substances capable of being absorbed or elaborated by the intestinal mucosa.

6708 THE INFLUENCE OF GASTRIC SECRETAGOGUE SUBSTANCES ON CARBONIC ANHYDRASE. (Fr.) Dobrescu, D. (Inst. Med. Pharm., Bucharest, Rumania). Arch. Int. Pharmacodyn. 166(1):167-171, 1967.

When 1.5×10^{-9} M of insulin, 10^{-5} M of reserpine or 10^{-4} M of bethanechol chloride were added in vitro to a rat stomach homogenate, carbonic anhydrase production was activated. The activation seen was less than that produced by the addition of 10^{-4} M of histamine under the same experimental conditions. When 10^{-6} M of acetazolamide was added in addition to these gastric secretagogue substances, the activation of carbonic anhydrase was totally inhibited. Although it is possible that this release of carbonic anhydrase produced by insulin, reserpine and bethanechol chloride could be due to a direct action on stomach cells, it is probably due to the release of histamine caused by these substances. The in vivo corresponding conc. in the rat of these 3 gastric secretagogues would be 1.6 U/kg of insulin, 6 mg/kg of reserpine and 18.2 mg/kg of bethanechol chloride. These in vitro responses were measured by electrometric recordings of pH changes.

6709 CONTRIBUTION TO THE STUDY OF ACID HYPERSECRETION OF THE STOMACH AFTER PORTACAVAL TRANSPOSITION IN THE DOG (CONTINUED). PERSONAL EXPERIENCES.

(Fr.) Hubens, A. (Free U. Brussels, Belgium). Acta Gastroent. Belg. 29(12):1110-1164, 1966.

The effects of portacaval transposition were studied in dogs with Heidenhain pouches, the Thiry-Vella preparation or vagal isolation. Local anesthesia of the intestinal mucosa (xylocaine in 2% epinephrine soln.), before application of the stimulus, markedly inhibited gastric secretion; vagal anesthesia almost completely abolished the secretory response of the Heidenhain pouch to chemical stimulation of the isolated intestinal segment in dogs with portacaval transposition. Under these conditions, parenteral atropine or i.v. secretin also inhibited the secretory response. The acid secretory response in Heidenhain pouches in dogs with portacaval transposition was not enhanced during irrigation of the intestinal segment with 10% N HCl in the presence of aminoguanidine. It is concluded that portacaval transposition reinforces the intestinal phase of gastric acid secretion, probably as a result of mediation by a histamine-like factor, and that liberation of this factor may be controlled by the vagus nerve.

6710 GASTRIC SECRETION AND ELECTROLYTE EQUILIBRIUM. (SERUM AND URINE SODIUM AND POTASSIUM.)

(It.) Maselli-Campagna, G. (U. Bari, Italy), V. Ronzini, S. Ferrarese and V. Giampetruzzi. Gazz. Int. Med. Chir. 72(1): 24-36, 1967.

A total of 25 fasting ulcer patients (18 men, 7 women; aged 27-73 yr.; 22 of 25 with duodenal ulcers, 3 of 25 with ulceration at the site of previous anastomosis) received pyrilamine (Neoantergan; 2.5 mg/kg, route not specified) 30 min. prior to admin. of 0.04 mg/kg histamine phosphate, s.c. Max. histamine response was accompanied by a statistically significant diminution of mean serum conc. of K (from 5.0-4.5 mEq/liter) and a definite, but not statistically significant, diminution of mean urinary conc. of K (from 52-45 mEq/liter). A similar effect was not exerted on either serum or urinary conc. of Na, nor was there any significant relationship between the total urinary excretion of Na and the total amount of acid found in the gastric juice. It is concluded that the reduction of serum conc. of K represented an effect of the antihistamine and a failure of the organism to compensate adequately for the loss of K which it induced in the gastric juice.

6711 ACTION OF ATROPINE UPON THE STIMULATED GASTRIC SECRETION OF THE RAT.

(Ger.) Lick, R. F. (U. Munich, Germany), W. Brückner, O. Beck and W. Hart. Med. Klin. 62(11):414-417, 1967.

A total of 200 female rats (200-220 g) were used in groups of 10; the pylorus was ligated (Shay preparation) preserving as far as possible the local blood circulation. Gastric juice was collected for a period of 6 hr. In addition to measurement of the vol. of basal secretion, the vol. secreted under stimulation of histamine, prostigmine, insulin, tetrapeptide and gastrin was determined without and with the admin. of atropine. Each sample of gastric juice was analyzed for HCl in mEq/hr. and for the number o U/hr. of pepsin by the usual methods. The basal secretion was not significantly depressed by atropine; despite a small decrease in secretion vol., the conc. of the secreted acid was increased. The stimulating effects of prostigmine insulin, tetrapeptide and gastrin were inhibited significantly by atropine, tending to approach the basal values, with prostigmine-atropine secretion falling below the basal atropine value for vol., acid, and pepsin. Histamine-atropine secretion, however, decreased about 33% in vol. and pepsin conc. only 6% in HCl conc. as compare to secretion stimulated by histamine alone. Thi suggests that action of histamine upon the parietal cells cannot be blocked by atropine. The treatment of acidity in ulcer cases by nontoxic doses of atropine is ineffectual and not warranted in clinical practice.

6712 THE SECRETORY FUNCTION OF THE STOMACH FOLLOWING INJECTION OF HISTAMINE, GASTRIN AND SYNTHETIC TETRAPEPTIDE INTO THE SYSTEMIC CIRCULATION AND INTO THE PORTAL VEIN. (SECRETORY STUDIES ON THE HEIDENHAIN POUCH).

(Ger.) Lick, R. F. (U. Munich, Germany), K. H. Welsch, W. Hart, W. Brückner, D. Balser and T. Gurtner. Z. Gastroent. 5(1):7-12, 1967.

Three dogs with vagotomized gastric (Heidenhain) pouches were provided with intraportal catheter via a mesenteric vein; the catheters were brough out of the peritoneal cavity and passed into the intrascapular region by s.c. tunneling, brought through the integument and anchored. After determination of the basal secretion (vol., mEq H and U of pepsin, all per hr.), the same paramete were measured with infusion of 3 different gast stimulants in 45 ml of 0.9% NaCl each, infused over a period of 1 hr.; each stimulant (histami 0.075 mg/kg; gastrin, 0.5 μg/kg and tetrapeptid 6 U/kg) was infused 3 times in succession into each animal, first by the intracaval route (via the femoral vein), second by the intraport route, and third by the intracaval route. In this manner the effect of the passage through the liver was determined. The introduction of histamine into the systemic circulation resulte in the av. increase of 300 times that of the basal secretion, actually to 36 ml, 6.6 mEq. HCl and 6300 U pepsin/hr. By contrast, the infusion of histamine into the portal vein resulted in only an increase of 10 times the

sal secretion to 0.5 ml, 0.30 mEq HCl, and 250 U
psin. The normal liver reduced the effect of
stamine by more than 90%. The comparable tests
ing gastrin gave a consistent, quantitatively
d qualitatively similar, secretion, 20 times
eater than the basal with infusion by either
ute, i.e. there was no hepatic action on gas-
in. Tetrapeptide stimulation was reduced 75% in
ssage of the stimulant through the liver.
fusion over the systemic route caused a 40-fold
crease in secretion, whereas over the portal
ute the increase was only 10-fold.

13 ACTION OF CAFFEINE-CONTAINING AND
CAFFEINE-FREE COFFEE UPON DIGESTIVE
NCTIONS. (X-RAY EXAMINATIONS OF SECRETION AND
TOR ACTIVITY OF STOMACH, INTESTINE AND GALL-
ADDER.) (Ger.) Glatzel, H. (Max Planck Inst.,
rtmund, Germany) and K. Hackenberg. Med. Klin.
(16):625-628, 1967.

group of 10 healthy men, 19-66 yr. old, under-
nt a double-blind test, 6 at a time receiving
eparations 3 and 4 and 4 receiving preparations
and 2. The preparations comprised: 1, 200 ml
caffeine-containing coffee; 2, 200 ml of
ffeine-free coffee; 3, 200 ml of caffeine-contain-
g coffee, 100 g of white bread and 30 g $BaSO_4$
12 g H_2O; 4, 200 ml caffeine-free coffee, 100 g
white bread and 30 g $BaSO_4$ in 12 g H_2O. The
ffee was a standardized brew drunk at a tempera-
re of 50-55°C containing 208 mg caffeine or
5 mg ("caffeine-free"). Although attempts were
de to quantitate the results, they can be
pressed only in general terms. The effect of
fferent pH values upon the amount of caffeine
sorbed by 30 g of $BaSO_4$ was measured *in vitro*;
om pH 3-pH 7.5 the value was fairly constant
an av. of 19%; as almost all the free caffeine
s absorbed in the stomach, only the absorption
the lower acid range was germane. No dif-
rences between the caffeine-free and the caffeine-
ntaining brews (preparations 1 and 2) could
discerned in the stomach with respect to the
rameters studied. When 100 g of white bread was
nsumed (preparations 3 and 4), caffeine-free
ffee produced only a small vol. of gastric
cretion, but a markedly more rapid passage
rough the small intestine than caffeine-contain-
g coffee. Motor activity of the gallbladder
s stimulated more by the caffeine-free brew
an by that containing caffeine. The X-ray
terminations were not sufficiently quantitative
these measurements.

14 EFFECTS OF CHANGES OF BLOOD CALCIUM
LEVEL ON GASTRIC SECRETION. INFLUENCE
THE VAGUS NERVES AND THE ANTRUM. EXPERIMENTAL
D CLINICAL STUDY. (Sp.) Milanese, J. C.
amos Mejia Hosp., Buenos Aires, Argentina) and
J. L. Morel. Rev. Argent. Cir. 11(2):39-41,
66.

2 dogs, a Heidenhain gastric pouch was created
d antrectomy was performed. The effect of

hypercalcemia (induced by admin. of large doses of vitamin D) on gastric secretion was then studied for 9 and 15 wk., resp., prior to sacrifice. The hypercalcemia did not induce a significant increase of gastric secretion or free acid and there was no evidence of gastric hemorrhaging. Studies made of patients, with or without gastroduodenal pathology, who received i.v. perfusions of Ca gluconate soln., yielded similar results. In patients with gastroduodenal disorders who were not operated, the curves of gastric secretion obtained in response to max. histamine stimulation were essentially comparable to those obtained by i.v. perfusion of Ca gluconate, although histamine stimulation resulted in somewhat greater increase of free acid. In patients who had undergone antrectomy and vagotomy for similar disorders, a significant postoperative decrease of total gastric secretion was observed, which was not affected by admin. of histamine, Ca gluconate or insulin.

6715 EXOCRINE PANCREAS FUNCTION AND MODIFIERS OF RESPIRATION. I. ACTION OF MORPHINE, ALONE AND IN COMBINATION WITH SODIUM BICARBONATED WATER, ON PANCREATIC AND BILIARY SECRETION IN THE RAT. (Fr.) Debray, C. (Bichat Hosp., Paris), J. De La Tour, C. Vaille, C. Rozé and M. Souchard. Therapie 22(1):109-117, 1967.

Admin. in rats of 10-20 mg/kg of morphine (i.v.) depressed the respiration within 5 min. to approx. 60% of that initially recorded, but neither the flow of bile nor the excretion of bilirubin was altered. A slight, but insignificant increase in pancreatic secretion followed the morphine inj., as did a slight increase in pancreatic amylase excretion. When Vichy water was admin. (2 doses i.v. of 5 ml.; with an hr. between doses and the last dose being 15 min. prior to the morphine) in conjunction with the morphine, it did not modify the influence of morphine on pancreatic flow, but it did tend to antagonize the effect on amylase excretion. The admin. of the morphine did not modify choleresis in the rat, nor influence the composition of the bile. The fact that these results are in direct contradiction to previous reports on respiratory effectors can partly be explained by species difference in that the rat lacks a pancreatic vesicle, and the doses of morphine differed from previous work.

6716 EXOCRINE PANCREAS FUNCTION AND MODIFIERS OF RESPIRATION. II. ACTION OF CODEINE ALONE AND IN THE PRESENCE OF SODIUM BICARBONATED WATER, ON PANCREATIC AND BILIARY SECRETION IN THE RAT. (Fr.) Debray, C. (Bichat Hosp., Paris), J. De La Tour, C. Vaille, C. Rozé and M. Souchard. Therapie 22(1):119-128, 1967.

Admin. in the rat of 20 mg/kg i.v. of codeine phosphate caused a 15-20% increase in pancreatic secretion which lasted longer than 3 hr., with a slight increase in amylase flow in the pancreatic juices and a 30% increase in bile flow during the first hr. The conc. of bilirubin at first was slightly decreased by the admin. of codeine, but later an increase in conc. was seen as is typical with choleretic drugs. The frequency of respiration was reduced max. to 66% of the initial frequency within the first 5 min. When 2 doses (with an hr. interval) of 5 ml of Vichy water were admin. i.v. to rats, pancreatic secretion was also increased, amylase conc. was increased the third hr., but bile flow was not affected and bilirubin conc. was only slightly increased. When these 2 substances were admin. the increase seen in pancreatic secretion and bilirubin conc. by each did not produce an additive response. Under these conditions, no increase in amylase conc. was seen. The admin. of the Vichy water did antagonize the respiratory suppression caused by codeine.

6717 DISTURBANCES IN ENZYME PRODUCTION IN PANCREATIC DISORDERS.

(Ger.) Heinkel, K. (U. Erlangen-Nuremberg, Germany) and H. Spanknebel. Z. Gastroent. 5(1):26-32, 1967.

Altogether 59 rats were tested for serum amylase conc. following i.p. inj. of 0.3125 mg β-methylazoethylcholine (β choline)/100 g body wt.; 46 were tested after i.p. inj. of 0.2 mg prostigmine/100 g body wt. Tests were also made on 17 rats after ligation of the common bile duct near the duodenum, 13 animals with the ligation near the liver, and 18 rats with ligations at both sites. Finally enzyme disturbances were provoked after 24 hr. in the ligated animals by inj. of β-choline and prostigmine. The effect of sham operations upon blood amylase levels was tested. Amylase activity in the blood was measured by 2 methods (Richeterich's and Heinkel's). These methods gave somewhat different but fairly comparable values for the same blood. Prostigmine did not influence blood amylase conc. in nonligated rats. β-Choline caused an increase in amylase blood level of 3.6 times; the max. level was reached 60 min. after admin. of the drug. A ligature of the bile duct applied close to the liver did not increase the serum amylase level by itself. A ligature applied close to the papilla caused an increase of serum amylase within 2 hr. The application of ligatures at both sites caused less increase than the single ligature applied at the papilla. When the ligature was close to the duodenum prostigmine caused increased serum amylase. Vagal stimulation increased blood amylase most when the pancreatic juice entered the bile ducts. Application of the 2 different ligatures and the combined ligatures 24 hr. prior to β-choline and prostigmine produced the most marked effects; these effects occurred in the same relative order as the effects produced earlier.

6718 ISOAMYLASE CHANGES IN SERUM AND URINE OF WHITE RATS AFTER LIGATURE OF THE COMMON BILE DUCT.

(Ger.) Miholčić, M. (U. Sarajevo, Yugoslavia) and B. Večerek. Clin. Chim. Acta 16(3):383-388, 1967.

Isoamylases of urine and blood and in the extract of kidneys, muscles, liver, spleen, parotid gland and pancreas of white rats were subjected to agar gel electrophoresis for 30 min. The gel was 1.5% agar and 0.2% starch buffered at pH 8.6. Amylase zones in the agar gel were made visible with Lugol's iodine soln. Amylase activity was determined by a photometric method. Urine, serum and the organ extracts were obtaine from white rats; the extracts were made by homogenizing the organs in 1:5 0.9% NaCl. The supernatant, after centrifuging, was used for electrophoresis. After a 30-min. ligation of the common bile duct, a new isoamylase appeared in the blood serum. The isoamylases were separated into 2 general groups: 1 group situated at the cathodic end of the γ-globulins; the other group appeared in the α_2-β_2 globulin range Amylase from blood and urine were in the same fraction lying between the α_2- and β_2-globulins. The extracts of the parotid gland and the pancre occupied a fraction situated more toward the cathode between β_2- and γ-globulins. The nonidentity of serum and pancreatic amylases was shown by their electrophoretic separation from a mixture of the serum and pancreatic extract. Th extracts of liver, spleen, muscles and kidney ea showed 2 fractions, 1 in the region of serum and urine amylase, the other in a more cathodic regi With a refinement of technic these isoamylases c be further separated and identified. After the 30-min. ligation of the common bile duct the new isoamylase of the cathodic group appeared i the serum and also 1 with the same mobility in t urine; these reached their max. after 20-50 hr. disappeared 80-100 hr. after application of liga ture. It is unknown if the liver or the pancrea is the source of this new fraction.

6719 ISOAMYLASES OF HUMAN PAROTID SALIVA.

(E.) Wolf, R. O. (Nat. Inst. Dent. Res., U.S. Publ. Health Serv., Bethesda, Md.) a L. L. Taylor. Nature (London) 213(5081):1128-1129, 1967.

Parotid saliva was bilaterally collected from selected individuals (11) by using modified Carlson and Crittenden cups; 15 μliters of parotid fluid were subjected to electrophoresis at 4 milliamperes/gel for 60 min. at 2-5°C on a 7.5% polyacrylamide gel according to the meth of Ornstein and Davis. The buffer was a 0.025 tris (hydroxymethyl)aminomethane and 0.192 M glycine of pH 8.3. For a comparative study, rat parotid saliva was collected and similarly analyzed. A polymorphism was found in the human saliva; 5 parotid saliva isoamylase bands were found in 3 individuals, 6 in 6, 7 in 1 and 8 in 1 individual. Comparison of human and rat parotid saliva showed differences with respect to the rate of electrophoretic migrati

nd the amylases maintained a high degree of
utonomy when mixed; this suggests amylase
ifferences among genera. Zymogram of the
lectrophoretically-purified amylase illustrated
he resolving power of the polyacrylamide gel
olumn electrophoresis compared with that of paper
trip electrophoresis; where 1 amylase band was
ecovered from paper electrophoresis and then
ubjected to polyacrylamide gel electrophoresis,
bands were found. It is concluded that the
mylase isoenzymes are separated as 1 band during
aper electrophoresis at pH 8.6.

720 THE EXCRETORY FUNCTION OF ONCOCYTES.
CYTOLOGIC, KARYOMETRIC, AND ENZYME
ISTOCHEMICAL STUDIES. (Ger.) Rother, P.
Karl Marx U., Leipzig, Germany). Jahr. Morph.
ikr. Anat. 75(4):400-427, 1966.

ogs (21; 10-17 yr. old) were killed by inj. of
nesthetic, and the fresh tissue was immediately
ixed in a variety of fixatives suitable to the
pecific research. Some tissue was frozen and
ectioned with and without gelatin embedding.
fter sectioning the paraffin-embedded tissue
as stained by a number of different combinations,
ome fluorescent; some sections were impregnated
ith silver. Glycogen was determined in sectioned
issue by a number of methods as was the fat
ontent, saturated and unsaturated, and the
hosphatide esters. Tests were made for a total
f 9 different enzymes. Oncocytes, which are
ells containing oxyphilic granules situated in
he glandular epithelium, are regarded as tumor
ells by some and moribund cells by others.
hese cells were studied for more information
egarding their function. Their differentiation
egins at the base and proceeds toward the apex
ependent upon an intense multiplication of
itochondria. Oncocytes are polarized, which
ecomes evident on silvering, in the distribution
f mitochondria, in the localization of various
ydrolytic enzymes, and as a radiate differentia-
ion in nuclear areas in which ribonucleic acids
re conc. Appearances of apocrine or holocrine
ecretion in these cells of the epithelium have
othing in common with a secretory process.
mitoses may lead to binuclear cells. Oncocytes
how a rhythmic growth of nuclei which form 3
ifferent size classes, their relation being
:2:4. They contain DPN-diaphorase, mono-
mino-oxidase, beta-galactosidase, carbonic
nhydrase, adenosine triphosphatase, and non-
pecific esterases; cholinesterases and alpha-
lucosidase could not be detected; the oncocytes
re innervated cholinergically. Numerous
rguments militate against the interpretation of
ncocytes as degenerate, damaged, aged or dyschylic
ells. It is suggested that these cells serve
n excretory function, probably ionic.

YDROLYSIS IN THE INTESTINAL JUICE FOLLOWING A
ROTEIN MEAL. (It.) Barbara, L. (U. Bologna,
taly), G. L. Stracciari, G. Fontana and P.
zzaroli. Arch. Ital. Mal. Appar. Dig. 33(2):
39-199, 1966.

ollowing introduction of a sound into the first
oop of the jejunum, a normal, fasting subject
eceived a meal consisting of lactalbumin, 1
/kg in 300 ml water plus 1.5 g polyethylglycol.
ne intestinal content was then aspirated at
)-min. intervals during a total observation
ime of 2 hr. Enzymatic degradation of the
otein meal was still incomplete at the end of
ne observation period, as confirmed by the
esence of numerous polypeptides. All the
nino acids were demonstrable at 90 min. and
gain at 120 min. The study is reported
imarily to illustrate the possibility of mak-
g a direct study of digestive processes in the
ntestine.

736 TRYPSIN, CHYMOTRYPSIN, AND TOTAL
PROTEOLYTIC ACTIVITY OF PANCREAS,
NCREATIC JUICE, AND INTESTINAL CONTENTS FROM
E BOVINE. (E.) Gorrill, A. D. L. (Canada
pt. Agric., Fredericton, New Brunswick) and
W. Thomas. Anal. Biochem. 19(2):211-225,
67.

technic was developed to assay total pro-
olytic activity, or esterase activities of
ypsin and chymotrypsin in bovine intestinal
ntents, pancreas and pancreatic juice.
ypsinogen and chymotrypsinogen were released
om pancreatic tissue by homogenization in 0.15
NaCl containing 0.1% Triton X-100. The
mogenate was centrifuged and diluted to con-
in 0.3-1.0% of tissue. Pancreatic juice was
luted in saline to 0.25-0.75 mg protein/ml.
x. enzyme activity and stability were obtained
activating with a crude enteropeptidase soln.
ntaining 0.05 M CaCl$_2$ at 5°C for 2-6 hr. for
ymotrypsinogen and 5-7 days for trypsinogen.
e normal curvilinear response of enzyme conc.
d casein digestion was transformed to a linear
ocess by plotting absorbancy (A) and A 3/2, using
tyrosine standard at 280 mμ. The rate of
nzoyl tyrosine ethyl ester hydrolysis by
tivated pancreatic juice was approx. 2.2 times
eater in 4.7% methanol than in 26%, vol./vol.
ith benzoyl tyrosine ethyl ester dissolved in
% or 56% methanol). The interfering sub-
ances in intestinal contents that produced an
parent esterase activity, in the absence of
zyme substrates, were attributed to increased
rbidity due to Ca complexing with certain
etary constituents or bile salts, or both.
e addition of (NH$_4$)$_2$SO$_4$, CaCl$_2$ and adjustment
intestinal contents to a pH of 8 removed most
the interfering substances from the super-
tant and also augmented chymotrypsin and
ypsin activity in most samples.

6737 THE CARBOXYL-TERMINAL SEQUENCE OF PORCINE PEPSIN. (E.) Dopheide, T. A. A. (Rockefeller U., New York City), S. Moore and W. H. Stein. J. Biol. Chem. 242(8):1833-1837, 1967.

The carboxy terminal sequence of the single polypeptide chain of porcine pepsin has been determined using peptides isolated from tryptic and chymotryptic digests of the pepsin and its aminoethylated and trifluoracetylated derivatives. The 27 residues are: Ile-Leu-Gly-Asp-Val-Phe-Ile-Arg-Gln-Tyr-Tyr-Thr-Val-Phe-Asp-Arg-Ala-Asn-Asn-Lys-Val-Gly-Leu-Ala-Pro-Val-Ala. This terminal segment contains all 3 strongly basic residues in pepsin, 2 Arg and 1 Lys. Since there is no half-cystine residue in this segment, the crosslinking of pepsin by 3 -S-S- bonds occurs within a highly acidic sequence of about 300 residues in which a single His is the only basic residue. The absence of positive charges in this C-terminal sequence contributes to the alkali lability and acid stability of porcine pepsin.

6738 DETERMINATION OF THE LIPID CONTENT OF PLASMA AND PANCREATIC TISSUE AFTER AN EXPERIMENTAL FATTY DIET. SUBMICROSCOPIC AND CHROMATOGRAPHIC INVESTIGATIONS. (It.) Gasbarrini, G. (U. Bologna, Italy), F. Faggioli, L. Gandolfi and L. Frizziero. G. Clin. Med. 47(7):658-674, 1966.

In adult, male albino rats, 6 days of high lipid diet resulted in the deposition of masses of intensely osmiophilic, lipid material in the peripheral and basal cytoplasm of acinic cells of the exocrine pancreas, a phenomenon which was markedly increased after 10 days of such feeding and accompanied by the appearance of similar masses in the interacinic capillaries and in endothelial cells. Gas chromatographic studies of pancreatic tissue homogenates showed no significant differences between experimental and control animals at 6 days, as concerned fatty-acid content. At 10 days, however, the content of oleic acid had risen from 29.8-42.9% in experimental animals, accompanied by a significant decrease of the percentage content of all of the other fatty acids. At 6 days, serum oleic acid content had risen from 20.8-33.5%, in the experimental animals; at 10 days, it was 38.7%. At 6 days, mean values for serum linoleic acid had fallen from 22.7-14.7%; those for serum arichidonic acid, from 13.3-4.6%; at 10 days, these values stood at 15.3% and 4.3%, resp. It is concluded that the passage of lipid material from the blood into exocrine pancreatic tissue was confirmed by this study, not only because the lipid substances demonstrated by the electron microscope had the same morphologic characteristics, but also because of the simultaneous and essentially proportional modifications of lipid content demonstrated by gas chromatography in both tissue and plasma samples.

6739 LOCALIZATION OF THE ACTION OF THE DIGESTIVE ENZYMES IN THE INTESTINE. (E.) Fomina, L. S. (Inst. Nutr., Moscow). Bull. Exp. Biol. Med. 62(9):989-993, 1966. [Transl. Biull. Eksp. Biol. Med. 62(9):28-33, 1966.]

42 ACETYLCHOLINE AND CALCIUM ON MEMBRANE
PERMEABILITY AND CONTRACTION OF
TESTINAL SMOOTH MUSCLE. (E.) Hurwitz, L.
anderbilt U., Nashville, Tenn.), S. Von Hagen
d P. D. Joiner. J. Gen. Physiol. 50(5):
57-1172, 1967.

etylcholine elicited a sustained contraction
d increased K efflux in longitudinal muscle
olated from guinea pig ileum. Stepwise
creases in Ca conc. in bathing medium from
06-0.36 mM tended to reduce the increase in
flux, but had a complex effect on mechanical
sponse. Contractions produced by high conc.
acetylcholine increased or remained at a high
lue with increasing Ca conc. Contractions
oduced by low levels of acetylcholine also
proved initially, but were depressed again by
e highest Ca conc. introduced. In the
propriate conc., ethanol completely inhibited
e acetylcholine-induced contraction without
ducing the increase in K efflux. This effect
s reversed by Ca. Both extracellular Ca and
hanol depressed the large, transient increase
muscle tone developed by fibers preincubated
a high-Ca medium and then exposed to a Ca-
ee medium. These results suggest that extra-
llular Ca ions react with 2 different sites in
e membrane, a storage site and a stabilizing
te. A muscle contraction is activated by Ca
ns which diffuse from storage site to the
oplasm. This diffusion process is impeded by
ions reacting with the stabilizing site.
t of the stimulatory effect of acetylcholine
due to its ability to counteract the action
Ca at the stabilizing site.

3 THE INHIBITION OF INDUCED MOTOR
ACTIVITY IN TRANSPLANTED FUNDIC
UCHES. (E.) Brown, J. C. (U. British
lumbia, Vancouver, Canada), L. P. Johnson and
F. Magee. J. Physiol. (London) 188(1):
-52, 1967.

ree dogs with Bickel-type denervated fundic
uches and 6 with transplanted fundic pouches,
with Mann-Bollman duodenal fistulae, were
epared. The motor activity of the pouches was
asured with a low pressure Statham transducer.
ter was used to fill the pouches and the trans-
cer. Duodenal pH was measured by means of a
ss electrode introduced via the fistula. A
ber catheter was also introduced into the
odenum for admin. of various solns. Tris
ffer (30 ml of 0.3 M adjusted to pH 9.0) inj.
o the duodenum was used as a stimulant of
or activity. Cholecystokinin-pancreozymin
U/kg, infused i.v.), 10 ml of emulsified olive
, 30 ml of 0.5% peptone soln. introduced into
duodenum all inhibited Tris-mediated fundic
ch activity. In all cases, frequency of
tractions, percentage activity, and total
litude were reduced. The present experiments
firmed the previous observation that an alkaline duodenum increases the motility of fundic pouches. Since the inhibitory substances studied were active in transplanted pouches it is concluded that the inhibition as well as the stimulation is humoral in nature. Cholecystokinin, pancreozymin or both are suggested as inhibitory hormones.

6744 EFFECT OF VAGAL STIMULATION BY 2-DEOXY-D-GLUCOSE AND INSULIN ON GASTRIC MOTILITY IN DOGS. (E.) Tsukamoto, M. (U. Florida Coll. Med., Gainesville), F. Herrera, D. R. Kemp, G. S. Emås, E. R. Woodward and M. M. Eisenberg. Ann. Surg. 165(4):605-608, 1967.

Vagally-denervated Heidenhain pouches and isolated innervated antral pouches were prepared in 3 dogs, and continuity of the gastrointestinal tract was reestablished with gastroduodenal anastomosis. Tests began 1-3 mo. after recovery. After an 18-hr. fast, motility of pouches was recorded manometrically using a saline-filled balloon in the antrum and an open-tip catheter in the saline-filled Heidenhain pouch. Pressure changes and respiratory movements were recorded continuously. After a 15-20 min. basal recording, insulin (0.5-1.0 U/kg) or 2-deoxy-D-glucose (150 or 200 mg/kg) was admin. i.v. and blood sugar levels measured before and after drug admin. Three experiments with each drug were performed on each dog. At the conclusion of experiments, 1 mg atropine sulfate was inj. i.v., motility measured for 5 min. A motility index (Cooke and Grossman) was used in calculation of response difference to the 2 drugs, and the % change in motility was calculated for each 5-min. period (compared with control) as: % change in motility index = 100 x (motility index after - motility index before)/(motility index before). Insulin consistently and markedly suppressed (beginning at 25-45 sec., continuing 10-20 min.) and then stimulated motility in innervated antral pouches but had no apparent effect on denervated pouch activity. The degree of suppression was dose-related. Atropine blocked stimulation. The effect of 2-deoxy-D-glucose was less consistent than that of insulin, the major effect being stimulation without previous inhibition on innervated antral pouches. In 2 of 9, slight inhibition preceded stimulation. The suppression was of a lesser magnitude and shorter duration than that observed with insulin, and was not dose-related. Atropine blocked the stimulatory phase. This drug also had no effect on Heidenhain pouches.

6745 ELECTROMYOGRAPHY WITH A UNIPOLAR ELECTRODE IN THE HUMAN COLON IN SITU. (Fr.) Couturier, D. (Bichat Hosp., Paris), C. Rozé, M. Couturier-Turpin and C. Debray. C. R. Acad. Sci. (Paris) 264(2)(Ser. D):352-355, 1967.

Electromyography using a unipolar electrode in situ, recorded from the colon of 6 humans, demonstrated the presence of organized electrical activity analogous to that reported in the small intestine. The subjects were examined in the morning prior to eating by introducing the active electrode at the level of the sigmoid colon by means of a rectosigmoidoscope. Recordings were made which lasted, with regularity from 1-5 min. showing slow and regular variations in the potential with amplitude of 0.2-0.4 mV with a remarkably stable frequency of 9-11 cycles/min. The recording of this slow periodic phenomenon indicated that the colon musculature is under the control of one or several "pacemaker" zones. On the electromyograph, the synchronized appearance of larger waves indicated a discharge or depolarization of a group of muscle cells which did not correspond, however, with evidence of a muscular contraction which was discernible by a manometric method, but rather they were very prolonged (in the order of 10 sec.).

6746 EFFECT OF FOCALIZED ELECTROCOAGULATION ON BASIC ELECTRICAL ACTIVITY OF THE SMALL INTESTINE. STUDY IN RATS. (Fr.)

Rougereau, A. (Fac. Med. Pharm., Tours, France), J. Thouvenot and C. David. *C. R. Soc. Biol. (Paris)* 161(10):1923-1925, 1966.

Focalized electrocoagulation of the serous surface of the rat small intestine, involving complete destruction of muscle fibers in an area approx. 0.4 cm^2, 6 cm distant from the pylorus, resulted in creation of a slow-wave pattern resembling that of the pylorus in the region above the area of destruction; in completely anarchic slow-wave patterns in the region below it. Both changes were transient, lasting 5-6 min., with progressive, spontaneous normalization during the 7 min. following. Identical phenomena were observed when the area of destruction was located 18 cm from the pylorus. When it was performed at both sites simultaneously the initial response was an increase in the frequency and a decrease in the amplitude of the slow waves, followed by appearance of massive low-frequency fluctuations, occurring 4-6 times per min., upon which these new slow-wave patterns appeared to be superimposed. When electrocoagulation was performed simultaneously at 3, 6, 9, 12 and 18 cm from the pylorus, normal slow-wave patterns disappeared entirely, being replaced by much slower fluctuations of potential, occurring 4-6 times per min. with amplitudes of the order of 1 mV. Longitudinal stimulation by + 800 mV for 3 min., on the oral side, restored normal slow-wave patterns during the period of stimulation only. It is concluded that the basic electrical rhythm of the rat small intestine is established and/or coordinated at 2 focal points, approx. 6 and 18 cm, resp., from the pylorus, as suggested previously by electrophysiologic studies made during active absorption, and that, at these 2 points, a marked similarity of histochemical characteristics is demonstrable as between muscular and subjacent mucosal tissue, including the presence of SH groups and acidity in the mucus of the latter.

6747 MECHANISM OF VOMITING INDUCED BY APOMORPHINE. (Sp.)

Jiménez-Vargas, J. (Spanish Inst. Physiol. Biochem., Pamplona, Spain), M. Asirón and J. Voltas. *Rev. Esp. Fisiol.* 22(4):173-184, 1966.

In unanesthetized dogs, the ED$_{50}$ of apomorphine required to induce vomiting in the presence of an empty stomach was 12.15 μg/kg; in dogs allowed to ingest milk *ad libitum*, prior to the experiment, it was 12.16 μg/kg; in dogs which had been subjected to mediocolicular decerebration, it was more than 30 μg/kg. Vomiting began with a series of rapid respirations of somewhat greater amplitude than normal, followed by a prolonged (2-5 sec.) contraction of the abdominal wall, with or without simultaneous closure of the glottis. In experiments with an isolated glottis and tracheal cannula, it was established that closure of the glottis did not influence the increase in abdominal pressure mechanically, while studies of the glottis *in situ* confirmed that the moment of max. resistance did not coincide with that of max. abdominal pressure but rather with the act of inspiration. It was also confirmed that closure of the glottis coincided with a relaxation, rather than an intensification, of abdominal pressure. The immediate cause of expulsion of the gastric contents appeared to be an abrupt, simultaneous contraction of the diaphragm and abdominal muscles, occurring rhythmically and bearing a direct relationship to the respiratory rhythm, which tended to accelerate in the presence of gastric distention. When intragastric pressure was increased to 20-40 cm H$_2$O, by introduction of liquid or inflation of a gastric balloon, the amount of apomorphine required to induce vomiting was sharply reduced.

6748 EFFECTS OF GASTRIN AND ITS ANALOGUES ON ISOLATED SMOOTH MUSCLES. (E.)

Mikos, E. (Roy. Coll. Surgeons, London, W.C. 2) and J. R. Vane. *Nature (London)* 214(5083):105-107, 1967.

In a search for a smooth muscle preparation sensitive to gastrin, the response of various muscles to gastrin and its analogs was studied. Using a standard organ bath, the tissues were screened with gastrin II. From the rat, only the descending colon showed sensitivity (2-10 μg/ml); from the hamster, the stomach; from the cat, stomach fundus and descending colon. Rabbit and mouse tissues were not sensitive; pigeon small intestine sometimes contracted, chick rectum did not. Hamster fundus and rat descending colon were studied further with superfusion technics with: human gastrin I, hog gastrin II, and 4 analogs (one an analog of the c-terminal pentapeptide and the other 3, analogs of the c-terminal tetrapeptide).

uiactive molar potencies determined from
periments with the rat descending colon
owed gastrin I, gastrin II, and ICI 50,123 to
equiactive; ICI 51,864 was about half as
tive; ICI 51,251 was 1/40 as active, and ICI
,759 had no activity. On the hamster fundal
rip, ICI 50,123 was about twice as active as
strin I, gastrin II and ICI 51,864. The
lative potencies were similar to their reported
tencies on gastric secretion. In the hamster
ndal strip these effects were unaffected by
opolamine, mepyramine, hexamethonium, nico-
ne, and morphine. In the rat colon, the
tions of all the peptides were decreased or
olished by hexamethonium, scopolamine, and
morphine. It is concluded the action on the
mster fundal strip is direct and the actions
rat colon indirect, probably via preganglionic
olinergic nerves.

49 RELATIONSHIP BETWEEN THE SENSITIVITY
OF THE GUINEA PIG ILEUM TO HISTAMINE
THE VITAMIN C CONTENT OF THE ILEUM. (Cz.)
hdanecká-Soušková, M. (Res. Inst. Exp. Ther.,
ague) and F. Hbubá. Cas. Lek. Cesk. 106(8):
3-216, 1967.

e sensitivity to histamine of the ileum from
inea pigs on Lunde's scorbutigenic diet and
om those on the same diet supplemented with
tamin C (5 mg per day and animal) was compared.
e animals on the vitamin C free diet were
rvested after the appearance of clear
orbutic symptoms (18-22 wk). The contraction
the distal end of the ileum caused by
stamine and its vitamin C content were deter-
ned in parallel. The contractibility was
und to be not related to the vitamin C content
the food or the ileum. This was affected most
kely by other dietary factors. Lunde's diet
pplemented with sufficient amount of vitamin C
recommended for feeding of guinea pigs to be
ed for histamine titration.

0 PASSAGE OF ^{198}Au THROUGH THE SMALL
INTESTINE. (Cz.) Andrysek, O.
arles U., Prague), J. Šetka, P. Georgi, H. J.
z, H. J. Altenbrunn and H. Berndt. Cas. Lek.
k. 106(8):210-213, 1967.

ioactive gold (^{198}Au) was used as a tracer to
ermine how fast the intestinal content passes
ough the intestinal tract of man. From
-500 μc ^{198}Au (about 0.1 mg Au) in 100 ml of
er were admin. p.o. to 25 fasting volunteers
the speed of its passage through the
estinal tract was followed either by photo-
ntigraph or by scintillation camera. The
loidal gold was not adsorbed in the digestive
ct and the av. time in which it reached Bauhin's
ue was within 120 min. after admin. When
Au was admin. together with barium sulfate,
passage of the isotope was slowed down.
plementary experiments in rabbits revealed
t ^{198}Au is not adsorbed to the intestinal wall, but is dispersed in the intestinal content. It is unlikely that the motility of the intestine is affected by the very low dose of radiation absorbed during the experiment. The method described makes it possible to determine the time of passage through the intestinal tract under physiological conditions.

6751 EFFECTS ON GASTROINTESTINAL MOTILITY IN PATIENTS UNDERGOING NLA-II OR CONVENTIONAL ANESTHESIA. (CLINICAL DISCUSSION.) (It.) Calligari, G. (Hosp. of the Brothers and Sisters of Charity, Milan), A. Citro and G. Kunos. Acta Anaesth. (Padova) 16(Suppl. 3): 225-235, 1966.

An experimental group of 9 men and 17 women underwent cholecystectomy or gastric resection under "neuroleptic analgesia" induced by Fentanil (R-4263; Ed.-can not identify this one) + dehydrobenzoperidol (R-4749), while a control group of 12 men, 14 women, underwent similar surgery under conventional pentothal-nitrous oxide anesthesia maintained by continuous drip. Patients' ages ranged from 17-74 yr.; the duration of intervention ranged from 45-150 min. Postoperative nausea was decreased significantly among the experimental group: from 40-0% among males and from 36-13% among females. There was no vomiting in either group, among males; among females in the experimental group it was reduced from 36-13%. No significant differences were observed with respect to regurgitation of gastric juice, intestinal distention, gas pains or resumption of spontaneous defecation.

767 DIFFERENTIAL DIAGNOSIS OF JAUNDICE BY
MEANS OF A NEW HEPATOBILIARY
LEARANCE" TEST EMPLOYING BSP. (Fr.) Pasini,
(Ceccarini Hosp., Riccione, Italy). Acta
stroent. Belg. 30(1):69-72, 1967.

ong 10 patients with jaundice due to obstruc-
on of the biliary passages, the liver function
dex (method of Tura et al.; normal = 96-100%)
nged from 70-96% (9 of 10 below normal
nimum); the cholestatic index ranged from
4-32.4. Comparable tabulations among 10
tients with jaundice due to viral hepatitis
re 60-81% and 4.4-15.0, resp. Among 4
tients with hemolytic jaundice they were
.6-100% (3 of 4 within normal limits) and
2-2.5, resp. In general, the liver function
dex was diminished in the presence of jaundice
e primarily to damage of liver cells and the
olestatic index then varied directly in
oportion to the degree of accompanying
olestasis. In patients with jaundice secondary
obstruction of bile flow, the cholestatic
dex was increased and the liver function index
en varied directly in proportion to the extent
d/or seriousness of accompanying liver damage.
is concluded that determining both indices
multaneously can be a significant aid to
curate differential diagnosis.

68 CONCENTRATIONS OF BILE SALTS AT THE
CRITICAL MICELLAR CONCENTRATION OF
MAN GALLBLADDER BILE. (E.) Tamesue, N. (U.
kansas Med. Ctr., Little Rock) and K. Juniper,
Gastroenterology 52(3):473-479, 1967.

ecimens of bile, not containing blood, were
pirated from gallbladders during surgery of
patients with peptic ulcer (3), carcinoma
tomach, 1; colon 1) and cholelithiasis (1).
ntrifuged sediment of specimens was examined
croscopically for crystal and cellular content
l by paper electrophoresis to verify the
esence of macromolecular micellar components
l detect contamination by serum proteins.
ee specimens were entirely normal; 1 showed
race of serum protein. Fifteen dilutions of
h bile specimen (1/10-1/800) were prepared
h 0.9% NaCl soln. Three surface-tension
surements were made on each dilution within
hr. of collection; density was determined in
yknometer; ultracentrifugation analyses were
e. Chemical analyses included: total bile
ds; cholic acid; dihydroxy bile acids (as
difference between the previous 2);
spholipids; P; cholesterol; bilirubin. Sur-
e tension decreased rapidly and linearly
h increasing bile acid conc. until a point
re the slope changes, the critical micellar
c., occurring when added surfactant molecules
incorporated primarily into micelles and
rt little additional effect on air-water
erface. At higher conc., 1 or 2 additional
lection points were observed. In sedimentation
coefficient curves a dilution eventually was reached at which the sedimentation peaks of the macromolecular component suddenly disappeared. The lowest conc. at which a peak could be identified correlated well with the critical micellar conc. The former was thus considered to be representative of the critical micellar conc. in this system. Ranges were: pH, 7.02-7.59; surface tension, 82-233 dynes/cm; dihydroxy bile acids, 16.0-46.3 mg/ml; cholic acid, 8.6-49.4 mg/ml; total bile acids, 32.0-86.3 mg/ml; phospholipid, 21.5-51.8 mg/ml; cholesterol, 2.6-9.6 mg/ml; bilirubin 1.9-5.4 mg/ml. By ultracentrifugation and surface tension analyses at critical micellar conc., the av. for total bile acid was 1.3 and 1.6 mM/liter, resp.; for dihydroxy bile acids, 0.8 and 0.9 mM/liter; for phospholipid, both were 0.5 mM/liter. The results support the theory that the physicochemical nature of bile is reflected by micellar properties of bile salts. Although total bile salt conc. is reduced in cholelithiasis, it rarely falls below the critical micellar conc. value obtained in this study.

6769 THE EFFECT OF BILE OBSTRUCTION ON THE OXIDATION RATE OF ETHANOL IN THE RAT. (E.) Kiessling, K. H. (St. Goran's Hosp., Stockholm) and L. Pilström. Acta Physiol. Scand. 69(3):187-190, 1967.

One of paired rats had silk ligatures tied around the bile duct; the other received a sham operative placement and removal of a ligature under the bile duct. After 1 wk. the ligated rats showed signs of bile obstruction. One ml of 30% ethanol in physiological saline/100 g was inj. i.p. Beginning 15 min. after inj., 0.1 ml venous blood samples were taken from the tip of the tail every hr. up to 7 hr. The ethanol conc. of blood samples was determined spectrophotometrically with alcohol dehydrogenase and nicotinamide adenine dinucleotide. Ethanol disappeared more rapidly from sham- than from ligated rats. After the max. blood ethanol level had been reached, rates of disappearance were 0.49 and 0.29 mg ethanol/g blood/hr., resp. Max. ethanol conc. was higher in bile-obstructed than in sham-operated rats. It is concluded that the rate of oxidation of ethanol is impaired by bile obstruction. Obstructed rats also needed more time to regain their balance than did sham rats.

6770 CONTRIBUTION TO THE STUDY OF BILE PROTEINS BY ELECTROPHORESIS AND CHROMATOGRAPHY ON SEPHADEX GEL. (Fr.) Lambilliotte, J. P. (Free U., Brussels, Belgium) and M. C. Woussen-Colle. Acta Gastroent. Belg. 30(1):56-68, 1967.

Four distinct protein fractions were separated clearly in normal bile derived by puncture of the gallbladder at the time of surgery for other reasons. The first peak was considerably greater than the others (e.g.: scale value = 2.5), which, in turn, defined a long, "camel's back" curve (e.g.: scale values = 1.5, 2.0 and 1.0, resp.). In bile samples derived through a Kehr drain on the 7th day after surgery for calculi of the gallbladder and common bile duct, only 3 peaks were demonstrable, all occurring at scale values below approx. 0.5 and none appearing to be significantly greater than the others. ~~In samples~~ derived by puncture at the time of surgery for stenosing pancreatic cancer, 2 peaks were demonstrable, neither being predominant; in samples derived by puncture during surgery for acute or chronic cholecystitis and calculi, only a vaguely irregular plateau could be demonstrated. It is concluded that proteins may be filtered through or actually secreted by the mucosa of the gallbladder, and that this capacity may be severely impaired in the presence of pathology affecting this area directly.

6771 RESPONSE OF HEPATIC AND SMALL INTESTINAL BIOSYNTHESIS OF CHOLESTEROL TO NICOTINIC ACID AND ANABOLIC STEROIDS IN RATS.

(E.) Nakamura, K. (Dai' Nippon Pharm. Res. Co. Labs., Osaka, Japan), Y. Masuda and H. Nakamura. J. Atheroscler. Res. 7(2):253-256, 1967.

Male rats (200-220 g, 14-16 wk. old) were treated daily with p.o. doses of 5 and 20 mg/kg methyltestosterone and 7α-ethylthio-17β-hydroxy-17α-methyl-5α-androstano-(3,2-C)pyrazole (PS-179, a new orally active anabolic steroid) for 10 consecutive days, and 40 mg/kg nicotinic acid for 4 days. Ten µc/kg (1-^{14}C)sodium acetate (specific activity 16.4 µc/mM) was admin. i.v. into the tail vein 24 hr. after the last dose of methyltestosterone or PS-179 and 2 hr. after nicotinic acid. To determine peak time of incorporation into liver cholesterol, untreated controls were exsanguinated under ether at 0.25-32 hr. later. Recovery of cholesterol in liver and small intestine was between 92-97%. In fasting rats peak incorporation of ^{14}C into liver cholesterol occurred 1-2 hr. after inj. of ^{14}C, but no constant relationship was observed in non-fasting rats. Subsequently, all rats were fasted for 18 hr. and killed 1.5 hr. after inj. of ^{14}C. Incorporation time of small intestine was 10 times higher than liver, although conc. of cholesterol in both tissues were not significantly different. Action of drugs did not alter tissue cholesterol levels, but all decreased incorporation time of ^{14}C into liver cholesterol and increased it into small intestine cholesterol. Total cholesterol synthesis in liver and small intestine was not significantly altered by these drugs. Simultaneous determination of incorporation time into plasma indicates an apparent increase in PS-179 or methyltestosterone-treated rats, but no change in nicotinic acid rats. It is likely that change in incorporation of 1-^{14}C-acetate into both liver and small intestine cholesterol is unrelated to lowering of plasma cholesterol level with PS-179.

6772 INDUCTION OF HISTAMINE FORMING CAPACITY IN CANINE LIVER BY ENDOTOXIN. (E.)

Fukuda, T. (Chiba U. Sch. Med., Japan). Nature (London) 214(5083):107-108, 1967.

Adrenalectomized dogs were admin. i.v. *Salmonella typhosa* (10 µg/kg), were bled during profound shock and hepatectomized. Liver extract and dialyzed serum preparations were incubated with and without histidine (15 mg) and the histamine content was assayed using atropinized guinea pig intestine. Small, yet significant, histamine-forming activity was found in both the liver and serum preparations (considerably smaller values in the latter) of adrenalectomized animals who showed profound shock, liver engorgement and almost complete glycogen depletion. Only trace activity and absence of activity for liver and serum preparations, resp., were determined employing the same doses of endotoxin in intact dogs. without circulatory shock or liver engorgement and also in those in whom shock was prevented by cortisone treatment or in those made endotoxin-tolerant before the experiment. Shock sera with the larger values of histamine-forming capacity produced marked liver engorgement and depressor response when infused intraportally (40 ml) into normal dogs as compared to sera with a smaller capacity which produced only moderate engorgement with no depressor effect. The "shock-factor" was readily extracted from saline-soaked liver slices and found in the serum protein fraction precipitable by 20-34% saturation with ammonium sulfate. It is probable that the factor is an induced form of histidine decarboxylase.

6773 AN EXPERIMENTAL STUDY OF MICROSCOPIC AND SUBMICROSCOPIC LIPID INCLUSIONS IN HEPATIC CELLS OF THE MOUSE. (E.)

Parks, H. F. (U. Kentucky Med. Ctr., Lexington). Amer. J. Anat. 120(2):253-279, 1967.

A total of 142 young male and female CFW mice were subjected to various dietary regimens. Twelve mice, representing a normal nutritional state, were maintained on Purina laboratory chow until sacrifice; 31 mice were fasted from 1-5 days before hepatic tissue was taken, and 8 others were fasted 4 days and re-fed at 2, 3.5 or 8 hr. before sacrifice. The remaining mice all received special diets; they were usually weaned at 21 days of age, and fed a normal diet for 1 or 2 wk. before being given a special diet. A fat-free test diet containing 58% sucrose as carbohydrate was given to 48 mice for 4-9 days; 17 were fed the fat-free test diet for 6-9 days, and subsequently starved 24-48 hr. before sacrifice. The high-fat diets consisted of 75-90% fat-free test diet and 25-10% fat; 16 mice were fed for 3-8 days on a high-fat diet in which the fat

omponent (25%) was a hydrogenated (and there-
ore saturated) vegetable oil. Ten were fed for
period of 3-5 days on a diet rich in un-
aturated fats (10-25% corn oil). Two
orphologically distinguishable types of
smiophilic inclusions, lipid spherules of
icroscopic (1 μ) and submicroscopic (300-1000 Å)
imensions, were studied by electron microscopy
the livers of mice fed as described above.
issues were fixed by perfusion with osmium and
ost-osmicated at 37°C. Submicroscopic inclu-
ions were present in endoplasmic reticulum,
olgi complex, cytoplasmic vesicles near the
pace of Disse, and in the latter space itself.
e lipid of these inclusions was sufficiently
nsaturated to be fixed and rendered insoluble
postosmication in all mice, except those that
ere fed a diet rich in saturated fat or a fat-
ee high carbohydrate diet (which induces
nthesis of saturated fatty acids); in mice fed
e 2 latter diets, the central mass of the
clusions escaped fixation and was dissolved
ring dehydration and imbedding. Inclusions
ere thus shown to reflect the nature of the
tty acids most freely available in the cyto-
asm of the hepatic cell in a given physiological
ate. The submicroscopic inclusions were
entified as secretion antecedents, elaborated
the liver for export to the blood. The
rger lipid inclusions, which did not dramati-
lly reflect changes in the degree of
turation of fatty acids available in the
ver cell, were thought to represent a more
able storage pool of hepatic-cell neutral
pid.

74 EFFECT OF HEMORRHAGE ON HEPATIC POTASSIUM MOVEMENTS. (E.) Andersen,
(Cook County Hosp., Chicago, Ill.) and W. C.
oemaker. Proc. Soc. Exp. Biol. Med. 124(3):
0-847, 1967.

e immediate effect of a sudden, acute,
derate-sized hemorrhage (approx. 20% of blood
l.) on hepatic and extrahepatic splanchnic
vements of K and Na was studied in 20 experi-
nts on 12 unanesthetized mongrel dogs. Net
tes of hepatic and extrahepatic splanchnic
take or output of the 2 electrolytes were
lculated from arterial, portal and hepatic
asma flow measurements. There was an increase
plasma K conc. in the hepatic vein and portal
in 2 min., and in the splenic artery 3 min.,
ter hemorrhage. A significant increase in net
patic K output occurred in the posthemorrhagic
riod after 3-6 min.; a transient increase in
output of K from the extrahepatic splanchnic
ea was suggested. There were no consistent
anges in Na plasma conc. after hemorrhage;
vever, a transient hepatic uptake of Na in
period after hemorrhage was suggested. A
ansient increase in hepatic plasma flow was
served after hemorrhage. Such changes after
orrhage are similar to changes found after an
. of epinephrine, and it is suggested that
effects of an acute hemorrhage on hepatic K
movements may be the result of epinephrine action.

6775 PLASMA DISAPPEARANCE OF CONJUGATED AND UNCONJUGATED ^{14}C-BILIRUBIN IN THE RAT WITH OBSTRUCTIVE JAUNDICE. (E.) Ali, M. A. M. (Roy. Free Hosp., London) and B. Billing. Proc. Soc. Exp. Biol. Med. 124(2):339-342, 1967.

Three male Sprague-Dawley rats weighing 320, 280 and 300 g, resp., and whose bile ducts had been ligated 7-14 days previously were admin. unconjugated (^{14}C)-bilirubin i.v. at conc. of 0.46 μc, 0.73 μc and 0.77 μc, resp. Plasma disappearance curves of both the conjugated and unconjugated (^{14}C)-bilirubin fractions were determined using a modified Weber and Schalm technic. Over 70% of the (^{14}C)-bilirubin radioactivity in the plasma was present as conjugated (^{14}C)-bilirubin after 15-30 min. of inj. of the unconjugated label. The biological half-life of unconjugated (^{14}C)-bilirubin av. 53 hr. (50-60 hr.) and that of the conjugated form av. 34 hr. (30-38 hr.). This difference was explained by the clearance of conjugated (^{14}C)-bilirubin by the kidney.

6776 INFLUENCE OF DIFFERENT NERVOUS SYSTEM CHARACTERISTICS IN DOGS ON SOME FUNCTIONAL FEATURES OF THEIR BILE SECRETION SYSTEM. (Rus.) Klimov, P. K. (USSR Acad. Sci., Leningrad), V. K. Krasuskii and N. A. Krasuskaia. Zh. Vyssh. Nerv. Deiat. Pavlov. 16(6):1016-1021, 1966.

The process of filling and emptying of gallbladder studied in 18 dogs by i.v. choleography (iodipamide; 0.4 ml of 20% soln./kg) 5-180 min. after admin. of dye and 1-180 min. after ingestion of 50 g of raw egg yolk showed that the rate of filling of the gallbladder by contrast bile and of its contraction after egg yolk feeding depends on the properties of the higher nervous activity, degree of strength and equilibrium of nervous processes. In dogs with weak nervous systems, distribution of contrast bile in the bladder occurred markedly more slowly; gallbladder contraction was also slower and less energetic; excretion of bile was below that in the dogs with a stronger nervous system. In unbalanced dogs the gallbladder filling with contrast bile started relatively rapidly, but then was delayed and the phase of uniform shadow occurred later than in balanced dogs. Gallbladder contraction in unbalanced dogs occurred more slowly than in balanced dogs.

6777 THE EFFECT OF NICOTINIC ACID ON THE DEVELOPMENT OF LIVER REGENERATING ACTIVITY IN RATS WITH PARTIAL HEPATECTOMY. (E.) Šimek, J. (Charles U., Hradec Kralove, Czechoslovakia), A. Husáková, K. Lejsek, J. Kanta and M. Pospisil. Naturwissenschaften 54(10):251-252, 1967.

After partial hepatectomy the normal mobilization of free fatty acids from adipose tissue is repressed by infusion of glucose with or without insulin, accompanied by a depressed rate of hepatic regeneration. The effect of nicotinic acid which exerts a similar action on the mobilization of free fatty acids from adipose tissue was tested on regeneration of hepatic tissue. Wistar rats (220 g) were partially hepatectomized (60-70%). All operated rats were killed 30 hr. later, i.e., at the end of the initial period of mitotic activity. Control rats received no nicotinic acid; experimental rats were inj. with 50 mg/kg nicotinic acid, Group 1 immediately after hepatectomy, and Group 2 12 hr. after hepatectomy. Mitoses/1000 nuclei were: before operation, 0.85; control rats, 15.2; Group 1, 0.0; Group 2, 2.75. Liver (g/100 g body wt.); before operation 1.35; controls, 2.44; Group 1, 1.93; Group 2, 2.12. Total liver content (mg/100 g body wt., RNA): before operation, 10.5; controls, 21.3; Group 1, 13.3; Group 2, 17.9; DNA: before operation, 3.4; controls, 6.3; Group 1, 3.8; Group 2, 4.7. Thus nicotinic acid in the dosage used inj. immediately after hepatectomy exerted a significant, depressing effect upon the parameters measured; nicotinic acid, inj. 12 hr. after pH exerted a less significant effect. Nicotinic acid, which inhibits mobilization of free fatty acids, also inhibits regeneration of liver tissue.

6778 CHOLERETIC ACTIVITY OF P-CHLORPHENYLALKANOLS. (Ger.)

Grisk, A. (Ernst Moritz Arndt U., Greifswald, Germany), K. D. Thiede and B. Galle. Acta Biol. Med. German. 18(1):77-90, 1967.

A series of p-chlorphenylalkanols were investigated for choleretic and associated effects using white rats (180-250 g) fasted 12 hr. before a test. Bile flow was measured from a polyethylene catheter in the common bile duct under anesthesia. The bile fractions, collected in 10- or 20-min. intervals, were weighed and the percentage increase in choleresis calculated; analyses of the bile determined the amount of materials excreted by the liver. The chlorphenylalkanols were dissolved in 75% alcohol and inj. into the duodenum. Every dose was tested on at least 6 animals. In the determination of LD_{50} the undiluted substance was inj. i.p. by means of a microsyringe. The following substances in the bile were quantitatively analyzed: (1) Na and K; (2) bilirubin; (3) bile acids; (4) glucose; (5) glutathione. The action of chlorphenylalkanols on livers poisoned with CCl_4 was tested. The most powerful choleretic effect was shown by p-chlorphenylpropanol, structurally close to 1-phenylpropanol. Chlorphenypropanol was less toxic and twice as active as 1-phenylpropanol. The LD_{50} for chlorphenylpropanol (the most active of the group) was 1100 mg/kg i.p. The dosage range was 25-400 mg/kg; the lowest dosage (25 mg/kg) stimulated choleresis by 80%. The choleretic effect of chlorphenylpropanol was sustained, reaching its peak in 60 min., losing less than half the peak value in the next 60 min. and caused practically no change in the Na and K conc. of bile. Secretion of bile acids remained within the normal range; mg/kg of bile acids in the bile secreted in 90 min. by controls av. 162 ± 17; by chlorphenylpropanol stimulated animals: 146 ± 21. The agent increased bilirubin excretion by 45%. Blood glutathione increased very moderately while the liver glutathione remained normal. Blood glucose was increased by 30% and liver glucose remained normal. The actions remained proportionately about the same in CCl_4-poisoned and normal livers. The clearance of BSP was decreased by chlorphenylpropanol in both normal and CCl_4-poisoned livers. The spasmolytic activity was tested on spasm produced in the guinea pig ileum by acetylcholine, histamine and $BaCl_2$. Effective plasmolysis occurred with conc. from 5×10^{-6} to 5×10^{-8} mol/ml (M.W, 170.64).

6779 THE DETERMINATION OF SERUM BILIRUBIN ACCORDING TO FERRO AND HAM. (Ger.)

Gladtke, E. (Gutenbergstr. 24, Giessen, Germany) Z. Klin. Chem. 5(2):63-64, 1967.

This colorimetric determination of bilirubin depends upon the oxidation of the bilirubin in acid soln. to a blue dye catalyzed by $FeCl_3$. Ferro and Ham combined 3 reagents with $FeCl_3$ into a single reagent in the proportions, 90 g trichloracetic acid, 900 ml isopropanol (to extract the dye); 100 ml ethylenglycolmonomethyl ether (to dissolve lipids) and 1 ml of a 7.2% aqueous soln. of $FeCl_3 \cdot 6\ H_2O$. Ten parts of reagent were mixed with 1 part of serum, the mixture filtered after 5 min., and the dye measured after 30 min. at 660 mμ. The possibility of variable adsorption of dye to precipitated protein and a variation in the amount of dissolved dye with differences in serum protein conc. prompted 2 series of tests: In the first series with 8 mg% bilirubin conc., extinction coefficients of 644 mμ were variable and markedly smaller for preparations with 6 g% than 3 g% protein. In the second series soln. of bilirubin, 4, 8, and 16 mg% in aqueous soln. only, and in 3% and 6% protein were subjected to determination by the Ferro and Ham method and also by the diazo method of Jendrossik and Cleghorn. The extinction coefficients were strictly linear with respect to conc. in the diazo method and were identical for the same bilirubin conc. in water, 2 and 6% protein. The extinction coefficients were disproportionately depressed (by almost 50% in 6% protein) with increased protein conc. in determinations made by the method of Ferro and Ham. The method is not recommended by the authors.

6780 INCREASE OF LIVER WEIGHT AND LIVER GLYCOGEN FOLLOWING INFUSION OF OROTIC

CID AND ADENOSINE. (Ger.) Sickinger, K. (U.
ottingen, Germany), R. Kattermann and H.
annemann. Acta Hepatosplen. (Stuttgart) 14(2):
3-99, 1967.

ats (230-270 g) fasted 12 hr. had a polyethylene atheter passed into the superior vena cava via he left jugular vein; it was impossible for the nimal to remove the catheter through which 2-18 ml were infused/day for 4 days. The rats ere placed in 8 groups of 7-11 animals each. roup 1 received only Ringer's soln. (12 ml/day) hich in this and the other groups contained 5 U of heparin; Group 2 also received 100 mg f choline chloride/day; Groups 3 and 4 eceived in 2 doses of 4 hr./day the sum of 67 g of choline orotate containing 40 mg of orotic cid; 15 mg of adenosine, representing 8 mg of denine, was the daily additive in Group 4; in roup 5 which also served as a control group, 18 of a sorbitol soln. was instilled/day containg 6.6 g of sorbitol; Groups 7 and 8 received he same amount of sorbitol with daily additions Group 6 of 67 mg of choline orotate in the ourse of 2-4 hr.; Group 7 received 200 mg of noline orotate (120 mg orotic acid); Group 8 as instilled with 15 mg of adenosine/day. he animals were bled under anesthesia by heart ncture 96 hr. after the onset of the infusion. ts infused with orotic acid showed a significant rise of 20% of the liver wt. associated th a proportionate rise of the fat-free dry . A further significant increase in liver wt. 3%) occurred with a simultaneous infusion of mg adenosine/day. When sorbitol was infused th a low conc. of orotic acid, the increased y and wet wt. amounted to only 9%; when the ily dosage of orotic acid was raised to 120 a significant liver wt. increase of 18% sued. Addition of 15 mg of adenosine/day used a further increase of liver wt. to 26%; high dose of adenosine produced a more marked se. The liver nitrogen increased to a lesser gree; the material responsible for the creased wt. of the liver, formed or deposited the liver, did not have the nitrogen quisite for protein. Increased liver fat uld not be seen after infusion. In fasting imals orotic acid, especially orotic acid th adenosine, caused a rise of the liver ycogen 7 times as great as that seen in the ntrols. Sorbitol increased liver size.

781 CATHETERIZATION STUDIES ON THE
METABOLISM IN LIVER. (Jap.) Murata,
(Mie Prefect. U. Sch. Med., Tsu, Japan).
ppon Naika Gakkai Zasshi (J. Jap. Soc. Intern.
d.) 55(7):771-788, 1966.

vels of some substances in the blood taken om the hepatic vein, the hepatic wedged vein oth obtained by liver catheterization), the rtal vein and femoral artery were measured in gs after starvation for 14-18 hr. Blood ucose level was generally higher in the order hepatic vein, hepatic wedged vein, femoral artery and portal vein. Occasionally the levels from the hepatic wedged vein were higher than those from the hepatic vein. Although the level of portal vein blood was the lowest in most cases, it was the highest in some dogs, presumably due to gluconeogenesis in the intestine. Lactic acid level was higher in the order of portal vein, femoral artery, hepatic vein and hepatic wedge vein, while no difference was observed in pyruvic acid level among the 4 blood vessels. Serum total protein level was highest in femoral artery blood and was similarly lower in the other three. An inverse relationship was found in serum albumin conc. between portal vein blood and hepatic vein or hepatic wedged vein blood, suggesting the regulatory role of the liver on conc. No significant difference was observed in total cholesterol, phospholipid and neutral fat levels among the 4 blood vessels. Glucose (1 g/kg) was rapidly infused into the mesenteric vein in dogs, and the levels of the above-mentioned substances were determined. After infusion, the difference in blood glucose level between portal vein and hepatic vein or hepatic wedged vein was marked. No definite change was noted after the infusion in lactic acid, pyruvic acid, total cholesterol, phospholipid and neutral fat levels. Slow infusion of the same amount or rapid i.v. inj. of 0.2 mg/kg of glucose induced no significant difference among the blood vessels. Studies were then done in dogs with acute damage of the liver induced by the i.v. inj. of 0.3 ml/kg of CCl_4, 2 times. The dogs were then starved for 14-18 hr., and the levels of the substances were measured. Similar measurements were done also after 7 days of recovery. The blood glucose level was generally low in the dogs treated with toxic agent as compared with the normal level, the level being higher in the order of hepatic vein, portal vein, hepatic wedged vein and femoral artery, while the level was higher in the order of femoral artery, hepatic wedged vein, hepatic vein and portal vein at the recovery stage. No definite difference was observed among the 4 blood vessels in lactic acid, pyruvic acid and total protein levels in the blood at both stages. The protein level in the toxic stage was generally lower than that in the normal case. Cholesterol level was generally higher at the toxic stage and lower at the recovery stage as compared with the normal levels. Neutral fat level was lower at the toxic stage, and then increased; and cholesterol and neutral fat seemed to be liberated from the liver during the toxic stage. The opposite was found in the phospholipid level. Hepatic wedged venous pressure was 175 and 180 mm H_2O during the toxic and recovery stage, resp.

6782 COLLECTION OF MOUSE URINE OR BILE.
(E.) Pope, R. S. (U. Oregon Dent.
Sch., Portland). J. Appl. Physiol. 22(5):
1024-1025, 1967.

A flat-bottom, dome-top 2.5 ml reservoir of Silastic rubber, having a side-mounted length of Silastic tubing (internal diameter 0.025 inch) which can be connected to a cannula, with 0.1 ml dead space vol. of tubing and cannulae, was used. The whole unit can be autoclaved. The reservoir is implanted under anesthesia in a s.c. position in the lumbar region; the tubing is positioned to run ventrally along the s.c. plane, then through the ventral peritoneum; the peritoneum is closed around the tubing by a loose purse-string suture; a cannula is inserted directly into the urinary bladder or common bile duct. After recovery of the animal, fluid can be aspirated from the reservoir by a sterile needle inserted through the skin. Placement of domes was of no hindrance to the mice. Of 20 mice with cannulated bile ducts, 17 survived (av. survival time 22.1 days). Six of 10 survived when reservoir domes were connected to the common bile duct (av. 27.3 days, range 3-64). Six of 7 with cannulation of urinary bladder survived (av. 23 days). For max. urine collection the urethra should be ligated because urine was often lost by the oral route when this was not done. Flow of urine and bile stopped a few days prior to death. Domes should not be emptied completely, but if this is done, a small amount of sterile saline soln. should be inj.

6836 THE TRANSFORMATION OF DEOXYCHOLIC ACID INTO ALLODEOXYCHOLIC ACID IN THE RAT. BILE ACIDS AND STEROIDS 174. (E.) Kallner, A. (Karolinska Inst., Stockholm). Acta Chem. Scand. 21(1):87-92, 1967.

6837 THE OOGRAM IN EVALUATING RESPONSE TO TREATMENT IN PATIENTS WITH Schistosoma mansoni. REPORT OF THE EFFECTS OF SODIUM GLUCONATE AND ANTIMONYL. [DOCTORAL THESIS, PRESENTED TO THE DEPARTMENT OF CLINICAL THERAPY, SCHOOL OF MEDICINE, UNIVERSITY OF MINAS GERAIS.] (Por.) Sales Da Cunha, A. (U. Minas Gerais, Brazil). Rev. Ass. Med. Minas Gerais 17(1-4): 94-95, 1966.

A group of patients with schistosomiasis was treated with a combination of sodium gluconate and antimonyl (proportions not indicated; total doses of 20.0-35.6 mg/kg, i.v. over 6-8 days). At the time of report, 20 of 32 had been free of infestation for more than 4 mo., including 10 of 20 who had been under continuing observation for more than 1 yr.; 4 of 32 had experienced reinfestation and were currently receiving a second course of treatment; 8 of 32 failed to respond. It is suggested that higher dose levels might increase the percentage of favorable responses; however, the attempt has not been made in deference to the known toxicity of antimonyl.

6838 INHIBITION OF THE MOTILITY OF Proteus BY ANIONIC SURFACE-ACTIVE AGENTS IN THE DIAGNOSIS OF Salmonella, Shigella AND Escherichia coli ENTERITIS. (Ger.) Linde, K. (Friedrich Schiller U., Jena, Germany), M. Kittlack and G. Funk. Deutsch. Gesundh. 22(6):275-279, 1967.

Enteritis coli organisms were isolated from stool samples of 6.4% of 5260 infants, using the Winkle culture medium; 24% of these organisms were motile Proteus strains. Using a medium containing an anionic surfactant ("detergent indicator plate"), pathogenic coliforms were detected in 8.7% of the samples. The increased yield was statistically significant. Salmonelliform and shigelliform organisms of the typhus-paratyphus groups comprised 0.1% and 1.25% of the organisms, resp. The significantly increased yield of pathogenic bacteria in the detergent indicator medium was confirmed by analysis of 296 samples from known typhus-paratyphus carriers.

6839 RADIOISOTOPE SCANNING OF THE SALIVARY GLANDS. A PRELIMINARY REPORT. (E.) Gates, G. A. (U. Michigan, Ann Arbor) and W. P. Work. Laryngoscope 77(5):861-875, 1967.

A short review of diagnostic technics using radioisotopes is included. Salivary gland scanning has 4 uses: tumor recognition, tumor localization, tumor identification (much clinical experience required), and physiological evaluation. A study is reported on comparative uptake by the dog salivary gland of 3 radionuclides: Na^{131}I, ^{99}Tc-pertechnate, and selenomethionine (methionine with S replaced by ^{75}Se). Agents were inj. i.v. in Nembutal-anesthetized dogs and external measurements of thyroid, parotid and body background radioactivity were made before inj. and at intervals afterwards. Photoscans of lateral and ventral neck-face areas of each dog were made. Direct measurements of blood and tissue radioactivity of 4 other dogs were made. Parotid and submandibular glands were dissected from several dogs to determine normal gland size, wt., and position. Doses of 100, 200, and 500 μc ^{131}I were given to 4 dogs each (total 12). Parotid activity became apparent immediately, reached a max. at 24 hr., and decreased gradually. For 2 hr. after inj., thyroid and carotid counts were nearly equal, but at 24 hr. thyroid counts were 5-10 times greater than parotid. Parotid scan visualization was optimum at 24 hr., although scan size and gland configuration were smaller than anatomically observed. A dose of 500 μc was necessary to obtain the minimum of 2000 cpm required to produce statistically reliable scans. Doses of 200, 500, and 1000 μc pertechnate were admin. to 4 dogs each. Parotid activity was apparent immediately, plateaued at 2-4 hr., and 6 hr. value was equal to that at 1 hr. Corrected for decay, max. uptake was at 6 hr. Up to 2 hr. thyroid counts nearly equaled parotid, but at 6 hr. were one-third of parotid. Scan size and configuration were about equal to that of the actual gland. At each dosage level, scans were excellent. Selenomethionine was admin. (500 μc) to 3 dogs, but no salivary scan visualization was observed in 7 days. Advantages of pertechnate over ^{131}I and selenomethionine for radiosialography are stressed.

6840 CARMINE AS A SOURCE OF NOSOCOMIAL SALMONELLOSIS. (E.) Lang, D. J. (Harvard Med. Sch., Boston, Mass.), L. J. Kunz, A. R. Martin, S. A. Schroeder and L. A. Thomson. New Eng. J. Med. 276(15):829-832, 1967.

An epidemic of Salmonella cubana infection in an urban New England hospital was traced to carmine dye. It was found that S. cubana was not a rare serotype and laboratory technics were largely to blame for lack of recognition. Over a 16-mo. period 21 cases of infection were recognized. Most patients showed symptoms of gastroenteritis, some with fever, while several had only mild symptoms. Twelve of the nosocomially acquired infections appeared shortly after ingestion of 0.3 mg capsules of carmine powder used as a stool marker. Several other nosocomial outbreaks were reported simultaneously in other regions. Heating of carmine during commercial production was found to be inadequate to kill the bacteria. Insects from Central America, which are the source of the dye, seem to be the source of contamination. Carmine is also used in the coloring of drugs, food and cosmetics. It was found that ingestion of as few as 15,000 S. cubana organisms (there were 30,000/capsule)

be sufficient to begin significant and even
al infection, especially during impaired
istance, such as probably would be the case
a situation where fecal study was required.

41

THE INFLUENCE OF THERAPEUTIC DOSES OF CIBA 32644-Ba ON THE HEMATOPOIESIS OF
TIENTS WITH AMEBIASIS OR SCHISTOSOMIASIS.

.) Doyen, A. (U. Lovanium, Leopoldville,
go Republic), J. Léonard, S. Mbendi and J.
net. *Acta Trop*. (*Basel*) 24(1):59-77, 1967.

myelotoxic effects were encountered in 25
ients (of the Negroid race from the area of
shasa in the Congo) suffering from either
biasis or schistosomiasis who received 25-30
kg/day in 3 daily doses for 10 consecutive
s of nitrothiamidazole (CIBA32644-Ba).
ther a decrease in reticulocyte production
an increase in the clearance of plasma Fe
noted, regardless of the severity of the
dition, nor was a tendency towards medullary
oplasia noted. The values for granulocytes,
throblasts and megakaryocytes remained
phologically and quantitatively normal. How-
r, in 5 cases where a deficiency of glucose-6-
sphate dehydrogenase was noted in the red
ls, the compound seemed to provoke a
dency towards hemolysis, but this phenomenon
eared benign in most instances and did not
uire any change in treatment. In 7 cases,
chiatric disorders occurred which required
mination of treatment in 4 cases on the
enth day. The 22 patients with schistosomiasis
with *Schistosoma mansoni* and 2 with *S. hema-*
bium) ceased eliminating eggs 10-20 days after
treatment (5 of these have remained con-
lled 2-4 mo. later). Two patients with
bic abscesses improved rapidly with treatment
did one patient with severe amebic colitis.

42

INTESTINAL ANASTOMOSIS WITH N-BUTYL CYANOACRYLATE TISSUE ADHESIVE. (E.)

sumoto, T. (Walter Reed Army Inst. Res.,
shington, D. C.), R. M. Hardaway III, K. C.
i, F. Leonard, C. A. Heisterkamp III and
M. Margetis. *Surgery* 61(4):567-572, 1967.

ılt mongrel dogs (70) of both sexes were
vided into 7 groups according to anastomosis
ocedure and tissue adhesive as follows:
oup 1: invagination, adhesive, holding sutures
) dogs); A. proximal segment into distal
gment (37 dogs); 1) N-butyl cyanoacrylate
ingle application)-30 dogs, 2) amyl cyano-
rylate (single application)-2 dogs; 3) heptyl
anoacrylate (single application)-2 dogs; and
N-butyl-cyanoacrylate (repeated applications)-
dogs.; Group 2: invagination, adhesive only
dogs): 1) N-butyl cyanoacrylate-3 dogs, 2)
tyl cyanoacrylate-2 dogs; Group 3: submucosa
erting, adhesive, hold sutures-5 dogs; Group
submucosa everting, adhesive only-5 dogs;
oup 5: serosa inverting; adhesive, hold sutures-5 dogs; Group 6: serosa inverting, adhesive only-5 dogs, and Group 7: serosa inverting, suture only (conventional technic)-5 dogs. Groups 2-6 had the proximal segment into distal segment, and in Groups 3-6, n-butyl cyanoacrylate was used. All 30 dogs in which single application of n-butyl cyanoacrylate was used survived. Various degrees of adhesion of the anastomosis to the intestine and omentum were seen at the area of anastomosis, but no kinking or obstruction occurred. The mucosa was united without evidence of luminal narrowing. There was a lesser degree of acute inflammation and residual polymer at the twelfth wk. as compared to the fourth wk. There was smooth union of the submucosa and each layer. In Group 2, 2 dogs in which heptyl cyanoacrylate monomer was used died 2 and 4 days after surgery. Two dogs in Group 3, 3 dogs in Group 4, 3 dogs in Group 5 and all in Group 6 died between 48 hr. and 14 days postoperatively. All in Group 7 survived. All dogs that died had anastomotic breakdown with signs of hemorrhage except 2 in which amyl or heptyl cyanoacrylate monomer was used. The av. time for the invagination anastomosis with use of cyanoacrylate tissue adhesive and 4 holding sutures was 7 min., as compared to 15 min. for conventional intestinal anastomosis. Application of tissue adhesives in intestinal anastomosis is dependent on the development of less toxic monomers and the development of a suitable technic; the method of intestinal anastomosis using a minimal number of sutures and a minimal amount of tissue adhesive provided a small collar of reasonable anatomical overlapping and maintained functional activity of the intestine. N-Butyl cyanoacrylate monomer, but not the other cyanoacrylate monomers, was satisfactory.

6843

THE EPINEPHRINE EFFECT IN ANGIOGRAPHY OF GASTROINTESTINAL TRACT TUMORS.

(E.) Kahn, P. C. (Tufts U. Sch. Med., Boston, Mass.), W. J. Frates and R. E. Paul, Jr. *Radiology* 88(4):686-690, 1967.

Arteriography of the celiac or mesenteric arteries or their branches preceded by admin. of epinephrine (5-30 µg depending on vessel size) was conducted for diagnostic purposes in 100 patients with known or suspected tumor of the gastrointestinal tract. Better tumor visualization was achieved in 23 of 50 patients using this technic. Contrast media was inj. usually within 3 sec. after epinephrine admin. Epinephrine resulted in a uniform decrease in blood flow in the hepatic and splenic trunks to 1 ml/sec. and 2 ml/sec., resp. Spleen length decreased approx. by 6%. Epinephrine response in gastric and pancreatic arteries was rapid and variable while the colonic arteries constricted more than those of the small intestine. Vessels of the gallbladder and pancreas were often unresponsive. Vasoconstriction generally remained marked for about 15 sec. and then diminished, resulting in a period of manifest hyperemia. No patient discomfort was associated with epinephrine inj. Vessels leading to a tumor were less responsive than normal arteries to epinephrine, which proved helpful in diagnosing primary liver tumors and vascular metastases to the liver. When arteries to a tumor provided only an inflammatory condition, epinephrine resulted in a "false negative" response. Variable response to epinephrine was manifested by pancreatic tumors, while some success was observed in carcinoma of the colon. Little success was noted in use of epinephrine in cases of gastric carcinoma. Use of this technic demands complete familiarity with the normal range of epinephrine effect in the gastrointestinal tract before application.

6844 INTESTINAL LYMPHANGIOGRAPHY IN VIVO. (E.) Nusbaum, M. (U. Pennsylvania, Philadelphia), S. Baum, B. Rajatapiti and W. S. Blakemore. J. Cardiov. Surg. 8(1):62-68, 1967.

An in vivo operative method for direct visualization of lymphatic drainage of the gastrointestinal tract of the mongrel dog is described. Evans Blue dye (0.5 ml) is inj. into the subserosal layer of the antimesenteric border of the intestinal segment under observation. A lymphatic channel conveying dye in the terminal arcade of the mesentery is dissected, isolated, and cannulated with a 25-30 gauge needle. Warm Ethiodol is inj. (3-5 ml at 1 ml/5 min.) as a contrast and the lymphatic vessel is seen to dilate. Progress of contrast during inj. is followed by fluoroscopic monitor. Inj. is discontinued when regional nodes or thoracic duct are opacified. X-rays are taken at completion of inj. and after 24 hr. Certain problems of extention to clinical use are suggested. The method requires an operative procedure and must be done at the time of associated laparotomy. The procedure may require 20-30 min. for cannulation and inj. of contrast medium. Media may be used as an adjunct to the operation in patients where the delineation of a block resection for carcinoma of the gastrointestinal tract might be of value as well as the study of certain obscure inflammatory diseases of the intestine, regional enteritis, and ulcerative colitis. Preliminary studies in patients at laparotomy confirm the feasibility of this procedure in the demonstration of lymphatic drainage of the gastrointestinal tract in man. Although unsuccessful to date, this method suggests the possibility of visualizing intestinal lymphatics by X-ray preoperatively following ingestion and absorption of iodized oil in the small intestine.

6845 ORAL GASTROINTESTINAL DIAGNOSIS WITH BARIUM SULFATE--AMIDOTRIZOATE COMBINATION. (Ger.) Glaser, F. H. (Martin Luther U., Halle-Wittenberg, Germany) and H. L. Kölling. Radiol. Diagn. (Berlin) 8(1):13-21, 1967.

The advantages and disadvantages of $BaSO_4$ suspensions and iodine-containing soluble contrast materials are outlined. A shortening of the time required for a complete X-ray examination of the gastrointestinal tract to 3 hr. while still retaining the contrast afforded by $BaSO_4$ is possible through use of a mixture of 185 ml of Esobaryte suspension (a suspension of very fine particles of $BaSO_4$ especially prepared for esophageal studies) and 16 ml of a preparation of amidotrizoate (Visotrast 370) compounded to correct its bitte taste. This combination was the result of numerous trials with Esobaryte, Laktobaryte, and the usual $BaSO_4$ suspensions mixed in different proportions with the amidotrizoate compound containing 325 mg of iodine/ml. The combination fulfilled the following requirement (1) In the region of the esophagus, the stomach and the duodenum, the degree of diagnostic certainty should be at least as great as with pure suspensions of $BaSO_4$. (2) The small intestine must be particularly well differentiated in structure and function. (3) The delineation of the proximal colon should be better than with pure $BaSO_4$. The examination of the entire gastrointestinal tract should be completed regularly 3 hr. after the intake of the contrast medium.

6846 CLINICAL EXPERIENCES WITH A STRICTLY FAT-FREE DIET SUPPLEMENTED WITH MEDIUM CHAIN TRIGLYCERIDES (MCT). (Dan.) Jarnum, S. (State Hosp., Copenhagen), H. Jense G. Bendixen and K. Bro-Jørgensen. Ugeskr. Laeg 129(22):718-722, 1967.

Medium chain triglycerides (6-12 carbon atoms) have been found useful in malabsorption where t pancreatic and biliary secretions are sufficien A fat-free diet supplemented by medium chain triglyceride has proven advantageous in 5 cases of protein-losing enteropathy; 15 patients with secondary malabsorption problems were also treated with medium chain triglycerid Of the 15 patients, 4 had undergone resection of the small intestine, 3 had pancreatic insufficiency, 3 unoperated terminal ileitis, 2 gastrectomy syndromes, and 3 had other less usual forms of malabsorption: retroperitoneal fibrosis with chylous ascites, intestinal sarcoidosis, and dermal and gastrointestinal mastocytosis. After a pretreatment period of 8 days on a normal diet containing 70-100 g of fat/day, the patients received a daily diet containing no more than 7 g of fat supplemented with 50-70 g medium chain triglycerides. The diet was adequate in terms of calories, proteins and vitamins, although the intake of linoleic, linolenic and arachidonic acids was low. The therapy was evaluated by fecal fat determinatio increase of wt. and clinical examination. The patients with protein loss had routine serum protein analyses. Albumin metabolism and intestinal loss of albumin were investigated using radioactive human albumin. All patients with protein-losing enteropathy showed improvement; in 4 of 5, wt. increased from 3-9 kg;

al fat in these 4 who formerly had
atorrhea (fat av. 17%) became normal (fat 6%);
thout steatorrhea showed no wt. gain. Serum
umin conc. increased; during the time of
atment intestinal loss of protein markedly
reased in 3 and completely stopped in 2 cases
was proved by loss of fecal radioactivity.
except 2 of the other 15 patients showed wt.
ns of 2-7 kg; 13 of these had steatorrhea
ore treatment; after treatment daily fecal
was 0-10 g in 12 cases (av 4.2 g/day); the 3
er patients had 61, 28, and 26 g of fecal
/day. Two patients with terminal ileitis did
improve with treatment; 2 with pancreatic
ufficiency did not improve until the treat-
: was supplemented with pancreatin.

7 RESEARCH ON PHYSICAL MEASUREMENT OF
AMYLASE ACTIVITY. (Ger.) Steger, W.
Clin. Erlangen-Nuremberg, Germany) and K.
nkel. Z. Gastroent. 5(1):37-41, 1967.

liminary studies on a number of preparations
waxy corn starch, almost 100% amylopectin,
luded some which required cooking and some
treated which could be mixed directly in cold
er, and a phosphate-esterified starch
ecial Starch 3828), easily dispersed in cold
er, and, when cooked, clear, homogeneous and
tral with persistent, high thickening qualities.
perature and age had less effect upon Special
rch 3828 than upon the others. It was chosen
the determination of urinary amylase conc.
terms of viscosity, measured in a rotation
cosimeter which indicated viscosity on a
le in 100 U. A number of trials with this
rch and pancreatin as powder and as soln.
wed 50 ml of 4% starch preparation to be the
t substrate vol. and conc. at 352 rpm of the
cosimeter at 37°C. When 2 ml of urine were
ed to 50 ml of 4% Special Starch at 352 rpm
at 37°C, viscosity fell linearly 11 U in 3
. The physical measurement of amylase
ivity can be done rapidly; the results in
ting urine samples are reproducible. Starch-
er preparations exhibit non-Newtonian
cosity, i.e. viscosity increases with the
ed of stirring. It is therefore imperative
t the speed be constant in these tests. No
relation is made between viscosity measure-
ts and U of amylase in the urine.

8 THE ACTION OF PANCREATIC EXTRACT UPON
STEATORRHEA IN LIVER CIRRHOSIS AND
ER SUBTOTAL GASTRECTOMY. (Ger.) Földes, J.
rst Med. Clin., Budapest), I. Magyar, J.
cs and G. Gyertyánffy. Z. Gastroent. 4(5):
-288, 1966.

est with ^{131}I-labeled triolein was made on
mal persons, on patients with chronic
creatitis or liver cirrhosis, and on patients
h subtotal gastrectomy and Billroth II
structions. The fasting test cases were
en 20 μc ^{131}I-triolein mixed with milk p.o.
The 72-hr. stool collection was measured for radioactivity expressed as a percentage of the ^{131}I-triolein dosage. Blood samples were taken 2,4,5 and 24 hr. after intake of labeled triolein and their radioactivity determined as percent/liter plasma. To prevent accumulation of ^{131}I in the thyroid, each patient received 5 drops of Plummer's soln. 2 times/day during the test. When steatorrhea occurred, the test was repeated while the patient received 2 tablets of pancreatic extracts (Cotazyme forte) 3 times/day. Of 38 controls, 35 showed less than 4% of the radioactive intake in the stool; 2 had 4-5% and only 1 had more than 5%. Four of 7 patients with chronic pancreatitis, 12 of 31 with liver cirrhosis, and 8 of 20 with subtotal gastrectomy had more than 5% radioactive fat in the feces. The oral intake of pancreatic enzymes reduced or rendered normal the fecal fat content in 5 of 12 cases of steatorrhea among patients with cirrhosis; the other 7 cases remained unchanged; improvement was seen in 6 of 7 patients with gastrectomy and steatorrhea following treatment with pancreatic enzymes; the seventh patient showed an increase of fecal fat. No mention is made of the effect of pancreatic enzyme treatment upon the 4 patients with chronic pancreatitis and steatorrhea. The radioactivity of the plasma correlated well with its decrease in the feces.

6849 CLINICAL STUDIES ON OXOMEMAZINE IN GASTROENTEROLOGY: ANOTHER APPLICATION IN ESOPHAGOGASTRIC PATHOLOGY. (Dut.) De Groote, J., L. Gomand and L. Van De Mierop. T. Gastroent. 9(4):371-378, 1966.

Oxomemazine, a hydrochloride of 9,9 dioxo-10, (2-methyl, 3-dimethyl aminopropyl) phenothiazine is white, crystalline, not hygroscopic, and readily soluble in water at 20°C; when dissolved it should be protected against the light. Its toxicity is similar to that of promethazine; its low toxicity allows its long term use even in pregnancy; it has no effect upon blood pressure and its effect on the CNS and the autonomic nervous system is minimal. It is a good antihistamine and also a contact anesthetic especially suitable for patients who complain of high epigastric pain which presents a diagnostic as well as therapeutic problem. A total of 44 ambulatory patients (23 men and 21 women) were treated with the compound in syrup, the total dose of agent being 15-20 mg/day divided into 3 or 4 smaller doses. Large doses cause depression. The drug was admin. over a period of 18 mo. The 44 patients, examined and diagnosed by clinical tests, radioscopy, and gastroscopy, had a variety of gastric disorders such as atrophy, hypertrophy, erosive gastritis, ulcers, esophagitis (sliding hernia). Forty patients had excellent and continuing relief from pain; 3 had no relief or relief for a short time only; 1 of these 3 had esophagitis and sliding hiatal hernia, 1 had an active ulcer and the third nausea and uremia.

GASTROINTESTINAL DISEASES

GENERAL

STUDIES ON SEROTONIN. 3. URINARY
EXCRETION OF 5-HYDROXY-INDOLEACETIC
IN PATIENTS WITH GASTROINTESTINAL DISORDERS.
) Civeira, F. (Fac. Med., Zaragoza, Spain),
iez-Antonanzas and R. Ballano. Arch. Fac.
Zaragoza 14(6):715-720, 1966.

e serotonin is produced by intestinal
ntaffin cells and high serotonin blood
ls occur in the presence of tumors of these
s (carcinoid tumors), the daily urinary
etion of 5-hydroxyindole acetic acid was
ied in patients with lesions of the digestive
t other than carcinoid tumors; this was done
scertain if there were any alterations in the
etion of this substance. The study included
atients with different conditions (glossitis,
tria, ulcer, diarrhea, exocrine pancreatic
fficiency, cholecystitis, cirrhosis, liver
is, portal hypertension and neoplasia). A
l of 419 determinations were performed, and
v. of 6.29 mg/day of 5-hydroxyindole acetic
was obtained, which is a normal-range figure
level in controls ranged from 3-13 mg/day).

EXPERIMENTAL STUDY ON THE CONGENITAL
INTESTINAL ATRESIA. A COMPARATIVE
Y OF THE MESENTERIC VASCULAR OCCLUSION AND
L PERITONITIS AS THE PATHOGENIC FACTOR.
.) Miyake, H. (Kyoto U., Japan). Nippon
Hokan (Arch. Jap. Chir.) 36(2):145-164,
.

ture of intestinal arteries caused necrosis
he small intestine in all adult guinea pigs
4 successive arteries which were supplying
n of the intestinal loop (23.8% of the entire
l intestine) were ligated. Scar formation
noted in the mesenteric membrane with
ture of fewer of the arteries in some animals.
ture of 5 successive secondary branches of
intestinal arteries supplying 16.5 cm of the
(11.5%) also caused necrosis in all animals,
e that of 4 branches supplying 15 cm (10%)
ed necrosis in one-half of the animals.
ases of ligature of successive secondary
ches of the arteries with concurrent block-
of the marginal arteries at each extremity
he intestinal loop, necrosis was induced
3 branches supplying 6.5 cm (4.5%) were
ted. Occlusion of fetal mesenteric arteries
made by ligature with additional cauterization
uinea pigs and dogs near the last fourth of
gestation period. The length of devascular-
intestine was approx. 15 mm in guinea pigs
30 mm in dogs. Only 8 of 51 animals
ated on continued gestation more than 24 hr.
r operation. An autospy of 8 fetuses thus
ined revealed various stages of degeneration
he intestine, such as adhesion, necrosis,
, in approx. proportion to the extent and
tion of intestinal ischemia. In order to
ce experimental fetal peritonitis in guinea
, turpentine oil (0.01-0.5 ml), bile
(0.03-0.05 ml) or stored blood (0.03-0.05 ml) were inj. into the fetal peritoneal cavity through the uterine wall with or without laparotomy of the mother animals. Only 1 of 18 animals continued gestation more than 24 hr. after the inj., although 17 survived. In the fetus which was inj. with the stored blood and kept alive in the uterus for 6 days, a small quantity of reddish-brown, turbid, ascites fluid was observed. Peritoneum and all intestines were stained the same color, but no adhesion was noted. Histological studies revealed mild congestion, edematous swelling of the serosa and infiltration of lymphocytes, neutrophils and monocytes into the submucosa and propria mucosa. These facts suggest a more inductive role of fetal mesenteric devascularization as the cause of congenital intestinal atresia than fetal peritonitis.

6906 BEHAVIOR OF EXCHANGEABLE POTASSIUM AFTER VAGOTOMY. EXPERIMENTAL STUDY. (It.) Lamarca, S. (U. Turin, Italy), F. Balzola, G. Giribone and A. Mussa. Minerva Gastroent. 12(3):83-85, 1966.

Three groups of rabbits, weighing 1.6-2.1 kg, received 60 μc ^{42}K, i.v., single dose, prior to determining the amounts excreted in 12 and 24-hr. urine samples. One group, which consisted of intact animals, served as controls. The drug was admin. to a second group 18 or 72 hr. after ileostomy; to the third group, before 15 or after 65 days after total, bilateral vagotomy. In the animals which bore ileostomies, the potassium peel (mg/kg) was reduced significantly. A significant reduction was also evidenced in the vagotomized animals which were tested within 15 days of intervention, but no significant deviation from control values existed in those which were tested after 65 days. Note is made that the results obtained with animals tested shortly after surgery may have been affected by shock and/or the effects of anesthesia.

6907 THE MODE OF INFILTRATION OF CELLS IN THE DIGESTIVE TRACT AND THE MESENTERIUM IN LEUKEMIA AND RELATED DISEASES. (E.) Honda, M. (Osaka U. Med. Sch., Japan). Med. J. Osaka Univ. 17(2):141-164, 1966.

Subjects were 76 cases of leukemia and other related hematopietic diseases, while controls were 30 cases of other diseases. The most common lesion was macroscopic bleeding in the intestinal mucosa. Ulceration and thickening of the mucosa were also observed. Leukemic infiltrations were most commonly found in the stomach, least often in the duodenum. In leukemia the lymph nodes and radix in the mesentery were larger than those in the peripheral zone. There was no relationship between the type of leukemia and these enlarged lymph nodes. Histologically, of 64 cases of leukemia, 23 had no infiltration of the digestive tract. In those cases with infiltration, the grade of infiltration was lower than that in the mesentery. There was a positive correlation between leukemic infiltration in the digestive tract and the mesentery. Leukemic infiltration of the digestive tract was of a lower grade than that of the mesentery especially with lymphatic leukemia. The existence of many cases of dissociation with the infiltration in the mesentery suggested that leukemic changes of digestive tract and mesentery were not related. It is concluded that there is no association with the systemic theory regarding the development of lymphatic leukemia.

6908 THE ROLE OF VENOUS OBSTRUCTION IN THE FORMATION OF INTRA-ABDOMINAL ADHESIONS: AN EXPERIMENTAL STUDY.

(E.) Belzer, F. O. (Guy's Hosp., London). Brit. J. Surg. 54(3): 189-190, 1967.

In 8 dogs, all the structures in 1 or more of the major arcades were surrounded with a cylinder of ameroid (a hygroscopic casein derivative), and animals were sacrificed 10 days to 3 wk. postoperatively. Massive adhesion was found in all, especially between loops of intestine and also to the surrounding structures such as omentum. At 10 days the adhesions could be separated by blunt dissection, although they were already highly vascularized and serosal surfaces produced a venous ooze. At 3 wk. adhesions were quite dense and could not be dissected free without damage to the serosa. Arterial pulsations were palpable in the arcade distal to the cylinder and arterial bleeding could be demonstrated from both cut ends when the involved arcade was transected distal to the cylinder. In 8 other dogs, 3 or 4 arcades were chosen at equal distances through the small intestine, the lymphatics ligated in 1 arcade, the artery in a second, the vein in a third. Controls received a sham operation of dissection around the base of the arcade, without ligation of lymphatics or vascular supply. At 2-3 wk. there were no adhesions of the intestine supplied by arcades with ligated lymphatics or sham-operated. Adhesions were found at 3 wk. in all vein-ligated arcades. Adhesions varied from none to slight and moderate in cases of arterial ligation. Number and density of adhesions varied directly with number of veins or arteries ligated. In 6 other dogs, 2 or 3 veins, each supplying an arcade, were ligated and intestinal manipulation was minimized. Adhesions were found at exploration at 3-5 wk. It is suggested that small and isolated venous thrombosis in the intestinal arcades might be an important etiological factor in postoperative formation of adhesions in man.

6909 ANEURYSMS OF THE AORTA: A REVIEW.

(E.) Fomons, J. J. (U. Miami Sch. Med., Fla.), F. T. Kurzweg and R. K. Broadaway. Ann. Surg. 165(4):557-563, 1967.

Of 7642 autopsies reviewed, 192 showed 249 (3.2%) aneurysms of the aorta or its major branches. Since none were found in 1495 below 25 yr. (19.5%), and only 3 were discovered in 646 of unknown age, the overall incidence in relationship to autopsies was 4.5%. Incidence was highest for Caucasian men, next for Negro men, but this was reversed for those of the ascending aorta. Locations were: ascending (22.1%); arch (11.6%); descending (7.6%); thoraco-abdominal (2.8%); abdominal (30.9%); iliac (4.8%); dissecting (17.3%); other (2.8%). Major causes of death were rupture, cardiovascu disease, gastrointestinal disease, respiratory disease, neoplasm, trauma, secondary aneurysm. The frequencies in relation to location were: ascending aorta 18.5%, 40.7%, 13.0%, 11.1%, 5.6 7.4%, 3.7%; aortic arch 32.1%; 25.0%, 3.6%, 25.0%, 3.6%, 0%, 3.6%; descending aorta 16.7%, 50.0%, 11.1%, 0% 16.7%, 0%, 5.6%; abdominal aorta 28.4%, 33.8%; 10.8%, 9.5%, 9.5%, 2.7%, 2.7%. In those of the ascending aorta, rupture caused death in 10 of 54 (1 wired for treatment Possibility of death by rupture increased with size of aneurysm: diameter less than 5 cm, 2.3%; 5-10, 11.5%; greater than 10, 44.4%; size unknown 20.0%; total 18.5%. Seven medium-size aneurysms contributed to death (12.9%). The rupture frequencies for those in the aortic arch were 0%, 16.7%, 44.4%, 50%, 32.1%, 32.1%. Combination of those causing and contributing to death was 31.4% in the former, 64.3% in the latter. One of 29 with aortic arch aneurysms was wired unsuccessfully. In 19 of the descending aorta only 3 (15.8%) ruptured. Of 74 of the abdominal aorta, 21 (28.4%) ruptured and caused death, no deaths without rupture. Of 43 dissecting aneurysms, 31 (72.1%) rupture and 3 (7%) caused major vascular occlusion and death. Causes of 3 deaths were unknown, of 6 others unrelated.

6910 MOTOR DIARRHEA FROM MEDULLARY THYROID CANCER. A NEW PATHOLOGIC ENTITY.

(Fr.) Bernier, J. J. (St. Lazare, Paris), M. Bouvry, D. Cattan and A. Prost. Bull. Soc. Me Hop. Paris 117(12):1191-1196, 1966.

Motor diarrhea, wherein the total intestinal transit time was only 3 hr., which had been unresponsive to treatment with either bismuth, lactic bacilli or derivatives of piperidine wa totally eliminated within a few hr. after the ablation of a medullary thyroid cancer. The diarrhea had lasted more than a mo. with only brief remissions and consisted of approx. 7 clear, yellow runny stools every 24 hr. There were no complaints of abdominal pain nor any other evidence of digestive troubles. However anorexia, asthenia and a 10-kg wt. loss (over period of 1 yr.) were noted. During examinati a discrete increase in the vol. of the superio pole of the thyroid was noted, although furthe sts gave no evidence of a hyperthyroid ndition. Scintigraphy revealed a nodule in at area which was removed and determined to be dullary thyroid cancer. The tumor was solid d not anaplastic, showing neither follicular r papillary differentiation (and thus non- creting) and contained high conc. of amyloid ostances in the stroma. Since the diarrhea eared up so rapidly after removal of the mor, it would seem that the tumor was producg a substance which caused hypermotility of e intestine. There has been no recurrence er the following 22 mo., even though thyroxin d to be admin. to compensate for a hypothyroid ate.

11 KIDNEY BIOPSY FINDINGS IN FAMILIAL CHLORIDE DIARRHOEA. (E.) Pasternack, (U. Helsinki, Finland), J. Perheentupa, K. uniala and N. Hallman. Acta Endocr. (Kobenhavn) (1):1-9, 1967.

rcutaneous renal biopsies were obtained with a n-Silvermann needle from 7 children (2 male, female; 1 mo.-3.5 yr. old) with familial Cl arrhea. Typical K-losing nephropathy was served in the 3 youngest children (1, 5 and 5 mo. old at time of biopsy), and nephro- lcinosis was found in all biopsies. Juxta- omerular hyperplasia occurred in all of the ildren. Arteriolar and arterial changes sembling those seen in hypertensive disease re also observed. On the basis of these find- gs, the following pathophysiological sequence suggested for this syndrome. Failure to sorb Cl in the intestine, possibly related to sence of the normal response of the intestinal cosa to aldosterone, leads to depletion of lt and H_2O though the intestine. The children us become hypovolemic, which in turn causes creased activity of the juxtaglomerular paratus as reflected in juxtaglomerular perplasia. An increased release of renin ads to a high blood level of angiotensin which imulates the adrenal cortical secretion of dosterone. This secondary hyperaldosteronism responsible for the observed high urinary K cretion which in turn leads to hypokalemic kalosis.

2 INTESTINAL (DUODENAL) MOTILITY IN RATS WITH CHRONIC CHAGAS' DISEASE. (Por.) nezes, H. (U. Sao Paulo, Brazil) and J. S. ira De Oliveira. Rev. Brasil. Med. 23(11): 9-782, 1966.

ur mo. after i.p. inoculation of approx. 0,000 Y-strain Trypanosoma cruzi, 5-mo.-old bino rats weighing 120 g were sacrificed and isolated segment of duodenum studied for sponse to stimulation by acetylcholine soln., 1-2.0 γ/ml. As compared to duodenal segments rived from normal controls, the test segments owed much increased irritability within the x. response range (0.3-0.5 γ/ml, for both groups), although significant differences were not evidenced at higher conc. levels. In both control and test segments, response was effectively blocked by atropine, 0.4-0.5 γ/ml. In control segments, the mean number of neurons in a 1 mm ring was 2362; in the test segments, it was 933, appearing to confirm a significant reduction in the number of ganglionic cells in Auerbach's plexus in the presence of chronic Chagas' disease.

6913 THE HEART IN PATIENTS WITH "MEGA" CONDITIONS OF THE DIGESTIVE APPARATUS. (Por.) Andrade, Z. A. (U. Bahia, Brazil) and S. G. Andrade. Hospital (Rio) 71(3):719-726, 1967.

Chagas' disease was found in 38 of 1600 pts. autopsied between 1951-1966, an overall incidence of 2.6%. Mega-esophagus was found in 15 of 38; megacolon in 7 of 38; both in 16 of 38 (accompanied by mega-ureter in 1 of 16). Among 13 of 38 (34.2%) dying with clinical symptoms of congestive cardiac insufficiency, macroscopic and microscopic evidences of chronic Chagas' myocarditis were demonstrable. Among those who died in the absence of such clinical symptoms, 16 of 25 showed microscopic evidence of incipient or chronic, interstitial myocarditis and 3 of 9 remaining showed chronic, degenerative changes of the intra-cardiac neural ganglia.

6914 ROENTGENOLOGIC CHANGES IN PROTEIN-LOSING ENTEROPATHY. (E.) Pock-Steen, O. C. (Copenhagen County Hosp., Glastrup, Denmark). Acta Radiol. [Ther.] (Stockholm) 4(6):681-689, 1966.

Ten patients (5 men, 5 women; 18-67 yr. old) with protein-losing enteropathy (Gordon's disease) were subjected to ordinary $BaSO_4$ roentgenologic examinations of the stomach, small intestine and colon. One patient had intermittent dyspepsia, edema and steatorrhea since childhood, whereas the others developed no signs or symptoms until adulthood. No specific features were observed in X-ray study of stomach and colon, but in all except 1 case, significant features were noted in the small intestine. The latter was generally dilated and appeared to fill the entire abdomen; there were broad, biconvex valvulae conniventes and a biconcave mucosal pattern, especially in the jejunum. Peristalsis was less marked. It is suggested that roentgenologic signs were probably caused by edema of the intestinal wall, particularly of the valvulae conniventes, where edema is more marked than in the corresponding grade of hypoproteinemia.

6915 HEREDITARY COPROPORPHYRIA. (E.) Goldberg, A. (U. Glasgow, Scotland), C. Rimington and A. C. Lochhead. Lancet 1(7491): 632-636, 1967.

Ten new cases (5 men, 5 women; 9-75 yr. old) of hereditary coproporphyria are presented, and the 20 other cases from the literature are reviewed. Massive excretion of coproporphyrin III in urine and feces, chiefly the latter, characterizes this disease. Hereditary coproporphyria may be provoked by barbiturates and possibly some tranquillizers and anticonvulsants into acute attacks resembling acute intermittent porphyria; during these an excessive urinary excretion of delta-aminolevulinic acid and porphobilinogen occurs. Analysis of stool porphyrin, supported by chromatographic and countercurrent technics, confirmed this unique biochemical nature of the disease. No clinical symptoms attributable to a porphyrin dyscrasia were found in approx. 50% of the cases; in the remaining 50%, symptoms suggestive of acute intermittent porphyria and, in 1 case, of photosensitivity, were found. The disease occurs in both sexes and at any age, and is hereditary (24 of 30 cases had a family history of the disease) in nature, transmitted usually as a Mendelian dominant trait. Based on hepatic and sternal marrow biopsy in 1 case, evidence was found that the disease is hepatic, not erythropoietic, in type. There was an association of psychiatric symptoms in 4 patients without other clinical symptoms of porphyria, thereby suggesting that a possible diagnosis of porphyria should be considered more frequently in psychiatric practice. The differential diagnosis from porphyria variegata and acute intermittent porphyria is given.

6916 ANIMAL EXPERIMENTS ON THE DECREASED MOTILITY OF THE SMALL INTESTINE IN PERITONITIS.

(Ger.) Lill, H. (U. Vienna). *Wien. Klin. Wschr.* 79(8):140-145, 1967.

Guinea pigs (350-450 g) were used to study the inhibition of peristalsis in experimentally induced peritonitis; a number of substances were tested for the induction of peritonitis; neither suspensions of talcum nor various dilutions of croton oil caused the condition. Hay infusions (0.3 ml/100 g body wt., i.p.), quartz sand (1 g dry) introduced into the peritoneal cavity, and *Klebsiella pneumoniae* (8×10^6 cells/ml, 0.1 ml culture/100 g i.p.) caused varying degrees of peritonitis with edema. Two control groups (saline inj. and uninj.), 1 group treated with hay infusion and 1 with quartz sand were made up of 20 animals each; the *Klebsiella* group had 28 animals. At intervals of 6, 14, 24, and 48 hr. after inj. of peritonitis agents, the animals were killed and the small intestine excised; 3-cm long segments of the lower ileum were taken: 1 for histology and 4 others for recording of muscular contraction under standardized conditions; the effect of 20 different conc. of acetylcholine, the strongest being 25 mg of the substance in 1 ml H_2O was tested on the small intestinal muscle. Although spontaneous motility of the intestine occurred in all experimental animals, the sensitivity to acetylcholine was reduced in peritonitis; however, it was possible to induce 100% contraction by increasing the conc. of the substance. The peristalsis of the small intestine can be initiated by proper medication in all cases of acute peritonitis.

6917 A VASCULAR PERMEABILITY DEFECT IN EXPERIMENTAL CHOLERA.

(E.) Keusch, G. T. (New England Ctr. Hosp., Boston, Mass.), P. Atthasampunna and R. A. Finkelstein. *Proc. Soc. Exp. Biol. Med.* 124(3):822-825, 1967.

Prepared purified choleragen was fed (50 µg) by stomach tube to infant rabbits pretreated by gastric lavage. At intervals (unspecified) aft admin. a single dose of Fe-dextran (1.25 mg/100 body wt.) was inj. i.v. in a vol. of 0.1 ml in femoral vein and the animal was sacrificed 10-6 min. later. Lengths (2-3 cm) of duodenum, prox and mid-jejunum, and ileum were removed, slit lengthwise, and pinned out on paraffin in formalin. After 24 hr. villi were scraped off and fixed to glass slides with Mayers egg album tissue was stained for Fe by Gomori technic and examined by transmitted light. In controls an Fe dose of 2.5 mg/100 g failed to produce observable staining of Fe in villi, even after immediate sacrifice. Gomori-stained sections from controls and treated animals not given the Fe-dextran were negative. Fe was detectable at min. after choleragen, and only 1 of 9 examined at 90-120 min. was negative. This was approx. hr. before initiation of overt cholera diarrhea and fluid was just beginning to accumulate in t intestinal lumen. Fe was localized almost entirely in the venular loop and was observed during the entire cholera syndrome. Of 34 animals sacrificed 2-24 hr. after choleragen, 3 were positive; of the 4 negatives, 3 were sacrificed at 2-2.5 hr. The fourth did not sho diarrhea, although a moderate accumulation of fluid was found within the intestine at 23 hr. Despite the clear contrast between control (12) and cholera animals (50), involvement in the latter was incomplete and not all villi were positive, with staining being spotty and decrea ing in distal specimens. The involvement of al the bowel showed the action of choleragen to be general, and the difference might be due to dilution, proximal binding, or inactivation of choleragen. The concept of cholera as a small intestine disease was supported by the lack of staining of colon vessels. An increase in vascular permeability, delayed in onset and prolonged in duration, was demonstrated. It is suggested that this alteration in permeability a major factor in experimental cholera diarrhea. Human testing is suggested.

93 REFLUX ESOPHAGITIS AS THE CAUSE OF HEARTBURN IN PREGNANCY. (E.)

Paula Castro, L. (U. Minas Gerais, Belo
rizonte, Brazil). Amer. J. Obstet. Gynec.
(1):1-10, 1967.

total of 88 women from the third-ninth mo. of
egnancy were divided into 2 groups: Group A
nsisted of 73 women who suffered from heart-
rn, and Group B, of 15 women taken as controls
l who never had any symptom of heartburn,
ther during pregnancy or in any other period.
Group A, of 60 patients interviewed, 31
.6%) referred to the beginning of heartburn in
e first trimester of pregnancy, 24 (40%) in
e second trimester and 5 (8.3%) in the last
imester. Of 62 cases studied, 49 (77.2%)
ported that food ingestion induced or
gravated heartburn, and recumbency aggravated
artburn in 82.2% of the cases. In 58 cases of
oup A, 12 were primiparas and 46 multiparas;
(77.9%) of the latter had experienced heart-
rn in preceding pregnancies. Each patient was
mitted to 1-4 tests: the acid perfusion
st, the acid reflux test, esophageal
piration and esophagoscopy. The acid
rfusion test was positive in 98% (49 of 50) of
e Group A patients and negative in Group B
tients; the acid reflux test was positive in
.4% (42 of 44) in Group A and in 13.3% (2 of 15)
Group B. The presence of acid, as revealed
esophageal aspiration, was higher (91%) in
oup A than in Group B (13.3%). Of 42 cases of
oup A studied by esophagoscopy, 40 (93%) had
phagitis, as compared to 1 of 3 in Group B.
stological study of 35 cases in Group A con-
rmed esophagitis in 32 (91.4%). Of 10 cases
om Group A submitted to upper gastrointestinal
diologic series, 7 were normal, and there were
ases of sliding hiatal hernia and 1 case of
stroesophageal reflux. It is concluded that
lux of the gastric contents into the distal
phagus with resultant esophagitis is the most
mon cause of heartburn in pregnancy.

4 THE GASTROESOPHAGEAL JUNCTION IN THE MONKEY AND ITS RELATION TO REFLUX.

) Karas, L. M. (Yale U. Sch. Med., New
ven, Conn.), H. Stern, D. Bloom, H. J. Binder,
Poindexter, W. Thayer and H. M. Spiro. J.
rg. Res. 6(11):469-477, 1966.

adult monkeys (Macaca mulatta) the effect of
rious surgical procedures including elimination
the esophageal sling (Group 1), esopha-
gastrectomy (Group 2), cardiomyotomy (Group 3)
l plication of the gastric fundus to the
dominal wall (Group 4) on the gastroesophageal
incter function is reported with special
phasis on gastroesophageal reflux. Reflux in
s study refers to passage of Ba from the
mach into the esophagus with or without a
vering of the sphincter pressure after
llowing. Postoperative Group 1 monkeys
showed no change in esophageal motility, nor change in the sphincter with respect to its preoperative location and characteristics, nor evidence of reflux with abdominal pressures up to 60 mm Hg. In Group 2 monkeys with subdiaphragmatic anastomosis, continual reflux was observed even in the absence of applied pressure and cleared briefly during periods of peristalsis. In addition, no sphincter was observed and intragastric pressure was transmitted into the stomach. Esophageal waves appeared at the point of respiratory reversal. Monkeys with intrathoracic anastomosis showed essentially the same findings as Group 2 except that esophageal waves were above the point of respiratory reversal. Group 3 monkeys showed the same results as those with intrathoracic anastomosis, except in 2 monkeys in which absence of reflux was consistently demonstrated despite application of abdominal pressure. After fundal plication, 2 normal lower esophageal sphincters were demonstrated. Reflux, which occurred frequently after plication, was diminished after normalization of fundal position.

6995 THE ASSOCIATION OF DIAPHRAGMATIC HIATAL HERNIA AND GASTROESOPHAGEAL CARCINOMA.

(E.) Michel, J. O. (Mayo Clin., Rochester, Minn.), A. M. Olsen and M. B. Dockerty. Surg. Gynec. Obstet. 124(3):583-589, 1967.

A study is reported on an attempt to determine whether or not there exists a cause-and-effect relationship between diaphragmatic hiatal hernia and gastroesophageal malignant disease. Of 398 patients with hiatal hernias observed for a number of yr., only 2 developed carcinomas. Of 163 patients with a primary diagnosis of cardioesophageal carcinoma, 16 had associated hiatal hernias. An earlier diagnosis of hernia was suggested in only 3 of these. In a group of 65 patients with concomitant diagnosis of carcinoma and hernia, it is suggested that in 70% the tumor probably initiated the hernia by shortening the esophagus. Only 6 patients seemed to have long-standing hernias. It is concluded that there is no causal relationship between esophageal hernia and subsequent development of gastroesophageal carcinoma. The incidence of carcinoma of the cardia may be increased when the esophagus is short.

6996 ACHALASIA CARDIAE: RESULTS OF HELLER'S OPERATION. A CLINICAL STUDY OF 55 PATIENTS. (E.)

Helsingen, N., Jr. (State Hosp., Oslo), O. Linaker and O. Kristiansen. Acta Chir. Scand. 133(1):35-39, 1967.

The 29 men and 26 women were 5-82 yr. old, with greatest incidence at 15-60. Diagnosis was by clinical picture, X-ray and esophagoscopy. Previous treatment with hydrostatic or pneumatic bag had been unsuccessful in the 7 attempts.

Operation was a modified Heller procedure: single anterior myotomy on the distal esophagus, with incision carried down beyond cardia onto the anterior gastric wall; laparotomy was performed in 38, thoracotomy in the latter 17. Postoperative clinical complications were infrequent. Supplemental dilatation treatment was necessary in 4 during the first 2 postoperative yr. Three died after operation, one from esophageal perforation at primary procedure; 1 from malnutrition; 1 following a resection of cardia, after several mo., because of esophagitis and stricture. Of 47 studied for 3 yr., 1 was lost to follow-up. The 46 were classified into 3 preoperative radiological states: I, moderate dilatation; II, gross dilatation; III, megaesophagus of sigmoid type. The number of patients who were better, same, or worse on X-ray examination was: I, 8, 2, 0; II, 20, 0, 1; III, 1, 6, 2; total 29, 8, 3. On clinical examination: I, 9, 2, 0; II, 22, 2, 2 (2 postoperative deaths); III, 7, 0, 2 (1 postoperative death); total, 38, 4, 4. More than 80% became asymptomatic or improved markedly after the operation. Reflux, clinical or radiological, was demonstrated in 9 (6 men, 3 women; 14-66 yr.). Hiatus hernia of the sliding type was demonstrated in 3. In these patients the symptoms were moderate and no further treatment was required.

6997 THE SIGNIFICANCE OF VERTEBRAL CHANGES IN THE PATHOGENESIS OF ESOPHAGEAL HIATAL HERNIA.

(It.) Lolli, L. (U. Perugia, Italy) and V. Pasqualucci. Ann. Fac. Med. Perugia 57(1):93-106, 1966.

Marked kyphoscoliotic changes were seen in 3 of 30 patients with hiatal hernia (12 men, 18 women; aged 30-70 yr.); moderate changes of the same kind were seen in 10 of 30; 16 of 30 showed X-ray evidence of arthrosis. It is suggested that kyphoscoliotic deviations of the spinal column, especially those occurring in the lumbodorsal region, may predispose to the development of hiatal hernia.

6998 THE HYDRODYNAMIC CHARACTERISTICS OF THE INTRAMURAL VEINS OF THE GASTROESOPHAGEAL JUNCTION IN THE PRESENCE OF ASCENDING BLOOD FLOW AND THEIR ROLE IN THE FORMATION OF ESOPHAGEAL VARICES.

(Por.) De Carvalho, C. A. F. (U. Sao Paulo, Brazil). Hospital (Rio) 70(6):1541-1561, 1966.

A study was made of 36 adult preparations and 20 derived from 7-9-mo.-old, stillborn infants, following inj. of various contrast media into the left gastric vein, the venae gastricae breves or the portal vein itself, thus simulating various degrees and conditions of portal hypertension resulting in an upward circulation of blood into the mucosal and/or submucosal vessels of the gastroesophageal junction. This study confirmed the presence of an essentially independent, intramural venous system in the inferior segment of the esophagus, of the rete mirabile type, which acted as an effectiv "hydrodynamic barrier" between the portal veno system and that of the superior vena cava. Thi rete mirabile system appeared to be complemente by several "short-circuiting" systems of vesse in the submucosa, pressed against the mucosal muscle sheath, while other vessels appeared to be regulated directly by the muscle sheath itself, through which they passed, and still others clearly represented preferential sites of venous dilatation when blood-flow began to set in a gastroesophageal direction in respons to increased portal venous pressure. It is concluded that the inferior segment of the esophagus, to a height which is not in excess of 4-5 cm above the epithelial transition line in adults, or 1 cm above it in the newborn, represents a functional terminal zone for veno circulation which is moving in an upward direction: i.e., from the portal vein toward the superior vena cava.

6999 NEW TECHNIC FOR VERIFYING THE PRESENCE OF GASTROESOPHAGEAL REFLUX.

(Por.) Pinotti, H. W. (Fac. Med., Sao Paulo, Brazil). Rev. Hosp. Clin. Fac. Med. S. Paulo 21(3):151-154, 1966.

Following insertion of 2 polyvinyl sounds into the stomach, 300 ml HCl (N = 0.1; pH = 1.1) were instilled and 2-3 ml gastric juice aspirated to determine the resulting pH. The sounds were then drawn up to the level of the gastricesophageal junction and 2-3 ml fluid aspirated through the proximal sound at points 1, 3 and 5 cm, resp., above the same. The opening of the distal sound, in turn, was maintained at the level of the inferior esophageal sphincter, in order to study its functioning i relation to esophageal motility. Among 5 norma controls (6 men, 4 women; aged 16-61 yr.) the lowest pH recorded in the esophagus was 5.0. Among 10 patients with retrosternal pyrosis secondary to hiatal hernia, surgery for megaesophagus, gastroesophageal anastomosis or Heller's operation (5 men, 5 women; aged 22-61 yr.), pH values ranged from 1.6-3.66. The only exception was a patient with hiatal hernia whos pH values at 1, 3 and 5 cm were 5.22, 2.56 and 1.95, resp.

7000 INCOMPETENCE OF THE CARDIA AND ITS RELATIONSHIP TO INFLAMMATORY CHANGES OF THE GASTRIC AND OESOPHAGEAL MUCOSA.

(Cz.) Šetka, J. (Charles U., Prague), B. Bednář, V. Potocký and H. Dvořáková. Cas. Lek. Cesk. 106(11-12):296-299, 1967.

The theory that the incompetence of the cardia is caused by decreased motility of the upper portion of the digestive tract was experimental verified. The motility of the digestive tract was impaired by insufflation with 50-60 ml of r of a balloon previously introduced into the omach or duodenum of volunteers. The changes the width of the terminal portion of esophas during swallowing due to the dilatation of omach or duodenum were then recorded by diocinematography. To some of the patients ropine (2 mg) or ephedrine hydrochloride (50) was admin. s.c. 10 min. before examination. e experimental impairment of the motility of e upper part of the digestive tract always led the impairment of the terminal part of the ophagus during swallowing. The admin. of the ugs mentioned above or the stretching of the omach by a large amount of contrasting material aSO_4) did not have a similar effect. In an tempt to determine how often the incompetence the cardia is accompanied by inflammation of e mucosa of the stomach or esophagus, samples gastric and esophageal mucosa were collected multaneously by biopsy from 52 patients with rdioesophageal irritation. Gastritis was tected in 84% of the cases. The incidence of ophagitis was much lower (15% of cases). The nclusion made by other authors that esophagitis incompetence of the cardia always develops om inflammatory changes of the gastric mucosa uld not be confirmed.

01 THE PROBLEM OF SO-CALLED CARDIOSPASM. (Ger.) Blaha, H. (U. Frankfurt/Main, rmany) and K. Reeh. Bruns Beitr. Klin. Chir. 4(2):138-151, 1967.

group of 61 cases of achalasia are reviewed in rms of (1) the condition of the esophageal cosa, (2) esophageal cancer, (3) pulmonary mplications. Despite statements to the ntrary, there is no causal relationship been existing esophagitis (15 cases cited) and e occurrence of achalasia; cardiospasm occurs the presence of a large range of mucosal nditions from the strictly normal to massive filtration of the musculature by leukocytes d thickening of the epithelium. Three of the patients had esophageal carcinoma, and the se of 1 is cited; the carcinoma had caused enosis in the upper-third of the esophagus ich interrupted swallowing. The esophageal rcinoma is often of very rapid growth; the tent of its interference with swallowing ries with location and size. The pulmonary mplications in cardiospasm were severe in ses only in diseased states of long standing d with extreme dilatation. The loss of lung nction caused by fibrosis induced by maintained spiration accompanying cardiospasm is not to underestimated. Every patient with cardioasm should undergo a thorough examination of e respiratory tract.

02 EXPERIMENTAL GRAFTS AS REPLACEMENT OF THE CERVICAL ESOPHAGUS. (Sp.) Corrao, (Italian Hosp., Buenos Aires, Argentina), A. Sivori, E. A. Sivori and T. Pirolo. Rev. gent. Cir. 10(5):209-211, 1966.

In a series of 25 dogs, 3 cm of the cervical esophagus were resected. Continuity of the organ was restored with a segment of bovine aorta in 6 animals, of homologous aorta in 7, with a Dacron tube in 6 and with an isolated, heparinized jejunal loop in 6. With the exception of the last group, results were unfavorable: the other animals died within a short time due to fistula, infection, complete stenosis and rejection or necrosis of the graft. Among the animals receiving a graft of autologous jejunal loop, 2 of 5 died on the second and twenty-eighth days, resp., following dehiscence of the grafted loop. When sacrificed at 2, 4 and 5 mo., resp., the remaining 3 of 5 were all suffering from stenosis of the esophageal anastomosis. In the light of these results and the clinical experience of the authors, it is concluded that the best material to replace a resected esophagus is a gastric section or a colonic or jejunal loop.

27 GASTRIC SUMP DRAINAGE WITH WATER SEAL MONITOR. (E.) Hughes, R. K. (Wads-
rth Hosp., Los Angeles, Calif.) and D. G.
otton. Surgery 61(2):192-195, 1967.

e use of a gastric sump tube with a water seal
ainage monitor was compared to standard gas-
ic drainage with a Levin tube. In use, a
uble lumen sump tube was passed into the
omach. One tube was connected to the water-
vered tube of a water seal drainage bottle.
v suction was placed on the bottle. In
eration air was drawn through the open tube of
e sump tube into the stomach where it and what-
er fluid present was pulled up the other tube
the drainage bottle. A continuous bubbling
the drainage bottle indicated the system was
operation. Two groups of adult male patients
eding gastric decompression were selected at
ndom. Ten received standard gastric suction.
e other 10 received gastric sump suction. The
np tube drained an av. of 723 ml/24 hr. com-
red to 622 ml/24 hr. for the Levin tube. The
np tube required an av. of 3.7 inj. of air and
5 irrigations/24 hr. The Levin tube was
rigated an av. of 7.9 times/24 hr. The nurses
volved expressed a strong preference for the
stric sump system. Cited as disadvantages are
e apparent need for large vol. of electrolyte
placement, longer periods of ineffective
ristalsis and later passage of flatus.

8 VISCOSITY OF WHOLE BLOOD AND PLASMA IN PROVOKED DUMPING ATTACK. (E.)
ristoffersson, E. (U. Goteborg, Sweden), C. M.
lenstam and B. Zederfeldt. Acta Chir. Scand.
(1):1-3, 1967.

rtially gastrectomized patients (6 men, 5
nen) with clinical dumping symptoms had dump-
induced by p.o. admin. of 150 ml 50% glucose
n. in the morning after overnight fast. Ten
samples of cubital vein blood were withdrawn
ore and 10, 20, and 30 min. after glucose
in. Hematocrit, whole-blood and plasma
cosity were determined. All 11 showed an
rease in whole blood viscosity which reached
. in 2 after 10 min., in 7 after 20, in 2
er 30. Differences of the max. changes from
trol values were 28%, 22%, 21%, 21% for shear
es 23, 46, 115, 230 sec.$^{-1}$, resp. Plasma
cosity increased in 8; unchanged in 3; av.
nge, 5%. Hematocrit increased from 41 to 42,
and 44 after 10, 20, and 30 min., resp.
se rate decreased from an av. of 76 beats/min.
ore induction to 89, 101, and 97 after 10, 20,
30 min., resp. There was no correlation be-
en the degree of symptoms (present in all 11)
the change in viscosity. Increase in whole
od viscosity seemed to be due mainly to
rease in hematocrit. The main effect of
nges on whole blood viscosity would be to
ggerate the difference in flow between
ferent regions.

7029 GASTRIC OUTLET OBSTRUCTION DUE TO CONGENITAL PYLORIC MUCOSAL MEMBRANE. (E.) Sloop, R. D. (Harbor Gen. Hosp., Torrance, Calif.) and A. C. W. Montague. Ann. Surg. 165(4):598-604, 1967.

A 41-yr.-old woman with postprandial nausea and bloating of 2-mo. duration, with vomiting in the last 10 days, is described. In the wk. preceding admission, diffuse epigastric pain and anorexia appeared and she lost 9 pounds. On admission the abdomen was distended, tympanitic and slightly tender; voluntary guarding was present; stool occult blood tests were negative. Abdominal X-ray showed a massively distended stomach, filled with food and gas, occupying most of the abdominal cavity, and descending to the level of S-1. Immediate treatment was aspiration of stomach contents (3 liter) through an Ewald tube; continuous nasogastric suction; i.v. fluids. After 8 days, overnight gastric residuals still measured 100-150 ml. Because of antacid therapy, no measurement of acid secretion was made. At operation (8 days) the antral-pyloric and duodenal serosa appeared normal. A longitudinal incision was made through the pyloric antrum, exposing and partially dividing the margins of an occluding transverse membrane 2.5 cm proximal to the pylorus. Membrane surfaces were covered with smooth normal mucosa and between mucosal layers was a thin layer of tissue continuous with and analogous to antral submucosa. An aperture (diameter less than 1 mm) through the thin and scarred central portion of the membrane was observed. Gastric musculature proximal to membrane was hypertrophied to the thickness of the pylorus. The membrane was divided, rather than excised, to prevent a circumferential scar. Posteriorly, the incision was carried into the proximal and distal antral mucosa; the longitudinal mucosal incision was closed transversely; the antrotomy was extended and closed as a Heineke-Mikulicz pyloroplasty; truncal vagotomy was performed. The postoperative course was uncomplicated, and the patient resumed normal eating habits. A review of the literature on membranous stenosis of the adult pyloric antrum and on pyloric membranous atresia is presented.

7030 NECESSARY THERAPEUTIC PRECAUTIONS IN THE ANESTHESIA AND REANIMATION OF PATIENTS WITH INFANTILE HYPERTROPHIC PYLORIC STENOSIS. (It.) Marangoni, G. (Civil Hosp., San Donà di Piave, Italy). Acta Anaesth. (Padova) 17(3):351-369, 1966.

A review of preoperative treatment, anesthesia, surgery and postoperative management of infantile hypertrophic pyloric stenosis includes 3 illustrative case histories, emphasizes the importance of correcting such biochemical disturbances as hypochloremia, alkalosis, hypokalemia, etc., prior to surgical intervention. The anesthetic procedure of choice is said to be orotracheal intubation.

7031 GASTRIC ANALYSIS AS A SCREENING MEASURE FOR CANCER OF THE STOMACH. (E.)

Gilbertsen, V. A. (U. Minnesota Med. Ctr., Minneapolis) and G. L. Knatterud. *Cancer* 20(1):127-133, 1967.

Gastric acidity by the tube-Toepfer technic in 3,239 seemingly normal persons over age 45 (median age was 55 yr.) showed achlorhydria in 708 subjects (22%), hypochlorhydria in 777 subjects (24%) and normal acid production in 1,754 subjects (54.1%). In measuring gastric acidity as a prognostic sign, 529 patients in a 9-yr. period with known gastric cancer were reviewed. Of these patients, 409 had undergone histamine gastric analysis (77%). There were 56 patients with a 5-yr. survival rate (10.6%). Of the 409 patients with gastric analyses, 46 patients (11.2%) survived more than 5 yr., while 10 patients (8.3%) of the remaining 120 patients without histamine analysis survived longer than 5 yr. Approx. 280 of 409 patients with stomach cancer would have been diagnosed by determination of their achlorhydria. Histamine analysis showed that 49 patients (12%) were hypochlorhydric, while the remaining 80 patients (19.5%) had normal acid values. The overall 5-yr. survival rate was 54%, 13% and 33% for achlorhydria, hypochlorhydria and normality, resp. The 5-yr. survival rate for the 409 cancer patients was 25 (8.9%), 6 (12.2%) and 15 (18.8%) for the achlorhydria, hypochlorhydria and normal groups, resp. Gastric analysis as a screening test was not practical in the early detection of gastric cancer, but did manifest significant prognostic value.

7032 GALLSTONES, GASTRIC SECRETION, AND FLATULENT DYSPEPSIA. (E.)

Capper, W. M. (Southmead Hosp., Bristol, England), T. J. Butler, J. O. Kilby and M. J. Gibson. *Lancet* 1(7487):413-415, 1967.

Of 50 patients observed with cholelithiasis, 26 gave evidence of gastric hyposecretion with the augmented histamine test. Of 18 patients with cholelithiasis and tested with the pyloric-regurgitation test, 16 showed persistent reflux of duodenal contents. Pyloric incompetence is usual in patients with gallstones, and gastric hyposecretion is also common. With gallstone formation, duodenal reflux may produce dysfunction and destruction of oxyntic cells. These changes usually cause hyposecretion, and the presence in the stomach of pancreatic juice and bile may cause flatulent dyspepsia. If cardiac incompetence is present, the passage of duodenal contents, with or without gastric juices, into the esophagus may produce heartburn. Pylorospasm is the commonly accepted mechanism of flatulent dyspepsia. It is suggested that the reverse is true.

7033 INTRAGASTRIC PHOTOGRAPHIC STUDY OF ANTIFOAMING AGENTS. (E.)

Hoon, J. R. (Sheboygan Clin., Wisc.). *Industr. Med. Surg.* 36(5):321-327, 1967.

Intragastric photography was by Gastrocamera with and without Fiberscope. The agents were admin. either after removal of camera (which had photographed unmedicated stomach) and followed by replacement of camera; or by inj. through a small plastic tube attached to camera or by p.o. insertion of camera and scope and inj. of material through transnasal Levin tube. The agents studied all contained simethicone. In *in vitro* studies the camera photographed tes drugs on freshly resected stomachs with peptic ulcer and on freshly resected autopsy stomachs, using (simethicone, 40 mg/tablet).
Young men (16-22 yr.) and several older men with gastritis were studied because of the known increase of mucus and mucus bubbling in younger subjects and those with gastritis. Studies with resected stomachs showed that a mass of bubbles could obstruct medication from mixing with an acid component and how this coul be overcome by an antifoaming compound. Clearing of the stomach from mucus bubbling was photographed by Gastrocamera 10 min. after admi of simethicone (dosage 8 drops). There was a marked reduction of mucus bubbling compared to premedication film. Existence of a time factor with some simethicone preparations was suggeste by the fact that at 10 min. after admin. of (simethicone 20 mg/ml) there was no destruction of bubbling, and this only occurred after a greater time interval. This time factor was studied using the head of foam on a glass of beer. It is concluded that in the preparations studied, simethicone usually produced a good reduction of mucus bubbling.

7034 VARIATIONS IN ARGENTAFFIN CELLS IN EXPERIMENTAL GASTRITIS. (E.)

Rodriguez-Olleros, A. (U. Puerto Rico, Santurce and R. Barroso-Moguel. *Amer. J. Gastroent.* 47(4):293-298, 1967.

Atrophic gastritis in rabbits was studied by inducing production of tissue-specific antibodies by sensitization with human gastric juic dialyzed at 2° for 72 hr. and dried under vacuum. Antigen was admin. (12 mg supernatant in saline soln.) i.v., biweekly for 12 wk. Papillomatous gastritis was induced in rabbits by instillation of 1.5 ml 0.5% croton oil in alcohol-ether (1:1) biweekly for 6-9 wk. Ulcerative gastritis was induced in dogs by admin. of 2 g cincophen twice in 1 wk.; animals were sacrificed 6-10 days after last dose. The stomach of each animal was fixed in formalin an sections made for staining with hematoxylin-eosin and with the argentaffin cell method of Barroso-Moguel. In atrophic gastritis, the argentaffin cells were definitely reduced in number. In papillomatous gastritis, there was an early necrotic phase during which the

rgentaffin cells were markedly increased.
ter approx. 12 admin. of croton oil, papilloma-
us growth began to appear and the argentaffin
lls became displaced. In ulcerative gastritis,
rgentaffin cells were absent in the edematous
crotizing phase, marked by appearance of
ripheral metaplasia in the mucosa. The
sults support the theory that the mesenchyma-
us cells of the gastric mucosa and other
milar cells in chronic infiltrates may
ntribute to the clinical picture of gastritis.
ey could also contribute to the histological
velopment of lesions as observed in the course
the various forms of gastritis.

35 THE EFFECTS OF NICOTINIC ACID ON
SEVERAL ASPECTS OF GASTRIC FUNCTION AND
THE HISTOLOGY OF THE GASTRIC MUCOSA. A
OPSY STUDY. (It.) Abbona, C. (U. Genoa,
aly), G. Peris, P. L. Gatto, G. C. Benzante,
Indiveri and A. Berretti. Arch. Maragliano
t. Clin. 22(4):425-438, 1966.

ngle doses of nicotinic acid (60 mg, i.v.; or
0-150 mg, p.o.) were admin. to a total of 20
bjects, aged 20-68 yr. (4 of 20 with normal
stric mucosa, as determined by biopsy; 8 of 20
th chronic, superficial gastritis; 6 of 20
th chronic, preatrophic gastritis; 2 of 20
th chronic, atrophic gastritis). The drug
duced a somewhat delayed, transitory increase
both the total vol. of gastric secretion and
e amount of free acid contained in it (in
rms of HCl/mEq/liter). The effect was some-
at greater than that induced by maintaining a
stric sound in situ for 1 hr. or by admin. of
ffeine and sodium benzoate (10 mg, single i.m.
se); it was less marked than that induced by
imulation with histamine chloride (1 mg, single
n. dose). Pretreatment with nicotinic acid
mg/day for 3-20 days, i.v.; or 150-200 mg/
for 8-15 days, p.o.) failed to influence
sponse to the other stimuli significantly.
en when pretreatment was prolonged to as
ch as 20 days, no significant changes in the
rmal gastric epithelium or gastric function
peared to result, although a reduction of
terstitial hemorrhaging was seen in the
stric mucosa of patients in whom this phenomenon
present.

36 MODIFICATIONS IN THE PYLORUS DURING
HIATAL HERNIAS IN THE ADULT. (Fr.)
rie, P., M. Cachin, F. Pergola, E. Parnaud
G. Le Gland. Arch. Franc. Mal. Appar. Dig.
(1-2):17-31, 1967.

15 cases of hiatal hernias, the classical
gical treatment was complemented by a
otomy and pyloroplasty. The pyloroplasty
sisted of an anterior pylorectomy followed
a vertical, linear suture which doubled the
meter of the pylorus and permitted examination.
palpation of the sectioned pylorus it was
nd to be hypertrophic in 9 cases ranging between 8-12 mm in thickness with massive hypertrophy in 2 cases. In 3 other cases the pylorus was sclerotic and in the final 3 cases it was found to be normal. Histologically, the hypertrophied pylorus produced a pseudomyoma with anarchic fibers which affected only the inner curvature. Much of the hypertrophy seemed to be due to edema which led to the impression that these lesions evolved from edema following muscular hyperplasia, terminating in sclerosis. The only clinical sign of this pyloric hypertrophy was a history of vomiting, indicating functional difficulty; such histories were noted in 7 of 10 cases. The hypertrophy seemed to be neither congenital nor secondary to the hernia, but would seem to explain the digestive discomforts often experienced after a regular hiatal hernia. It was concluded from these 15 cases, that from a therapeutic point of view a pyloroplasty should be added to the classical surgical cure of hiatal hernia in cases of pyloric hypertrophy, but vagotomy offers more disadvantages than advantages.

7037 THE PROBLEM OF QUALIFICATION FOR MILITARY SERVICE OF PAIN IN THE EPIGASTRIUM. (Fr.) Dupre, N. (R. Picque Hosp. Milit. Instruct., Bordeaux, France), C. Jean-Jean, C. Jeanneton, J. Peducasse, L. Girier and M. Couture. Bull. Soc. Med. Milit. Franc. 5:233-234, 1966.

Clinical, biological (histamine test for total acidity), radiological and psychological tests were conducted on 50 male patients (av. age of 20 yr.) who were hospitalized for gastroduodenal difficulties to determine their qualification for military service. Gastric ulcers were discovered in 16 of these patients of whom 50% presented a typical ulcer syndrome. In 57% the gastric chemistry revealed hyperchlorhydria, 37% presented a history of childhood gastric complaints, 58% were classified as presenting emotional immaturity and 37% gave histories of social and professional instability. Of the other 34 patients, 50% showed hypoacidic gastric chemistry while 29% showed normal gastric chemistry, 50% presented a history of childhood gastric complaints and 62% were classified as having neurotic personalities. Of those epigastralgic patients without ulcers who showed traits of a neurotic personality, 5 of 7 gave a clinical symptomatology of hyposthenic dyspepsia and 6 of 7 gave a history of childhood gastric complaints. Of these patients that were classified as having emotional immaturity, 50% gave a hereditary history of ulcers, 75% showed radiological evidence of gastrobulboduodenal lesions, whereas those dyspeptics with neurotic personality traits gave no significant history of hereditary ulcers and in 50% the radiological studies were totally normal.

7038 CHROMATOGRAPHIC ANALYSIS OF FREE AMINO ACIDS IN THE GASTRIC JUICE, USING

ION-EXCHANGE RESINS. (It.) Gandolfi, L. (U. Bologna, Italy), G. F. Piva and P. Vannini. Arch. Ital. Mal. Appar. Dig. 32(6):575-580, 1966.

The amounts of 21 free amino acids contained in gastric secretion following histamine stimulation were determined for a normal subject, a patient with chronic gastritic hypochlorhydria and a patient with gastric carcinoma, and expressed as functions of alanine = 1. In the normal subject, taurine, phosphoethanolamine, glutamic acid, tyrosine, leucine and phenylalanine were demonstrable in quantities ranging from 1.17-2.50 times the amount of alanine present; aspartic acid, threonine, serine, asparagine, proline and arginine were demonstrable in quantities ranging from 0.73-0.16 times the amount of alanine present; lysine and glycine showed values essentially equal to that found for alanine; valine, methionine, isoleucine, glucosamine and histidine were present only in trace quantities. In the gastritic patient, the alanine level was substantially the same as in the normal subject (200.93 versus 256.12 μg/100 ml, resp.); significantly increased were the levels of aspartic acid (from 0.49-1.24), threonine (0.32-0.78), serine (0.51-1.03), proline (0.73-1.67), leucine (1.28-2.26), phenylalanine (1.17-2.78) and lysine (1.00-7.65). The quantity of urea present was decreased from 32.64-14.76. In the patient with gastric carcinoma, urea was further decreased (to 4.20) and alanine was increased (from 256.1 μg%, normal subject, to 962.0 μg%). Also increased significantly, as compared to the normal subject, were leucine (1.28-2.18), arginine (0.16-0.86), phenylalanine (1.17-4.01). Decreased were phosphoethanolamine (2.13-0.20), taurine (2.50-1.46) and aspartic acid (0.49-0.14). Also increased significantly were several compounds found only in trace amounts in the normal and gastritic subjects: valine = 0.77, methionine = 0.25, isoleucine = 0.33, histidine = 2.59. The total amount of free amino acids was also increased markedly in the patient with gastric carcinoma.

7039 VASCULARIZATION OF THE PART OF THE STOMACH REMAINING AFTER OPERATIONS INVOLVING GASTRIC RESECTION. ANATOMICAL-RADIOLOGIC STUDY. (It.) Di Bartolomeo, A. (U. Rome, Italy) and L. Gioffrè. Ann. Ital. Chir. 42(11-12):1064-1075, 1966.

As compared with 5 control preparations, examination of 5 autopsy preparations derived from patients aged 30-50 yr. who had undergone gastric resection for gastric or duodenal ulcer confirmed the development of an extensive, anastomotic, parietal network of vessels which vascularized all of the remaining part of the stomach, as well as the site of gastroenteroanastomosis, in optimal fashion, appearing to preclude any likelihood of a patient's developing ischemia which might facilitate dehiscence of the anastomosis or delay of cicatrization. In all cases the source of the networ appeared to be the terminal branches of the gastr epiploic artery, emphasizing the importance of operating in such fashion that postoperative vascularization is not dependent upon anastomoses between the left gastro-epiploic artery and its right homonym, which tend to be either unreliabl or essentiallly inadequate.

7040 ENDOSCOPIC STUDIES OF GASTRIC DYNAMICS DURING THE EFFECTIVE PERIOD OF MEDICATION. EFFECTS OF WHOLE EXTRACT OF THE POSTERIOR LOBE OF THE PITUITARY. (It.) Mazzone, O. (U. Catania, Italy), A. Blasi and F. Sorrentino. Minerva Med. Siciliana 11(3): 57-58, 1966.

Posterior pituitary extract was admin. to 5 normal subjects and 5 who were suffering from chronic catarrhal gastritis. The group as a whole (6 men, 4 women) ranged from 29-55 yr. in age. In 1 of 10, the peristaltic wave was considerably decreased in force and its duration was appreciably prolonged. In 9 of 10, admin. of the drug was followed by a complete arrest of gastric motility, appearing within 4-10 min. and lasting 6-50 min. prior to the onset of gradual recovery. In all cases, both the pyloric sphincter and the walls of the antral region were relaxed significantly during the period when the drug was active. It is pointed out that these findings are directly at variance with the widely-held belief that this drug has a stimulating effect on the smooth musculature of the gastrointestinal tract.

7041 A STUDY OF SURVIVAL PATTERNS IN PATIENTS WITH GASTRIC CARCINOMA. (E.) Goldenberg, I. S. (Yale U. Sch. Med., New Haven, Conn.), J. M. Cohen and D. G. Skinner. Surg. Gynec. Obstet. 124(2):241-250, 1967.

In a 38-yr. study, 2- and 5-yr. survival rates were correlated with other patient data from 622 patients (male:female ratio 2:1) with confirmed adenocarcinoma of the stomach. An increased incidence was noted in elderly patients. Median age of female patients was 55 yr. (1921-1929) and increased to 65 yr. (1950-1959) while contrastin to 57 and 67 yr. in male patients for the same periods, resp. Poorer survival rates, which were not statistically significant, were observed in the lowest economic group and in tobacco users (no significant difference between cigarette and noncigarette smokers). Long duration of symptoms paralleled long survival rates. Survival time was significantly improved when the patient was in a state of good nutrition without demonstrable abdominal mass or hepatomegaly and had normal stool habits. Laboratory studies generally were not statistically significant when compared with survival rates. Gastrointestinal hemorrhage, occult or massive,

curred in 36% of the entire group and
ggested a continued use of routine stool
amination for blood. Survival was lowest in
tients who evidenced no roentgenologic
normality but who had proximal gastric lesions.
rvival time was increased generally when the
sion involved the lower half of the lesser
rvature, especially the prepyloric curvature
association with anterior surface involve-
nt to the level of the muscularis mucosae
ly. Attempted curative surgery as opposed to
lliative resection, max. tumor diameter of
9 cm and the absence of lymph node spread
re significantly related to an improved
ognosis.

42 GASTRIC AND SMALL INTESTINE DYSKINESIA AFTER VAGOTOMY. (Fr.)

Lortat-Jacob,
L. (Beaujon Hosp., Clichy-Paris), A. Cornet,
René, J. Guerre and L. Blanc. Bull. Soc.
d. Hop. Paris 118(2):187-193, 1967.

mplete improvement was obtained by the admin.
metoclopramide with the disappearance of the
skinesis which had followed vagotomies in 4
ses. Two cases included patients who had
dergone gastrectomies for duodenal ulcers
ose condition was complicated 1-8 yr. later
nausea, epigastric pain, diarrhea and wt.
ss; additional treatment was required.
e patient received 15 mg/day p.o. of meto-
opramide and the other, whose difficulties
re more severe, first received 20 mg/day i.p.
lowed by daily oral doses as improvement
curred. The other 2 cases concerned patients
o had undergone double vagotomies and gastro-
terostomies for treatment of duodenal ulcers.
these cases painful belching epigastritis
lowing meals, nausea, anorexia and, in one
se, diarrhea, began to occur 3-18 mo. after
rgery. The more severe case was treated with
mg i.p. as well as 3 tablets each day for 3
while the other case was stabilized by oral
blets 3 times a day. In 6 other cases the
. admin. of 10 mg of metoclopramide
cilitated the passage of any opaque medium
radiological exploration. These cases
cluded 3 esophagastrectomies for esophageal
ncer (2) and degenerated cardiac ulcers (1),
ith double vagotomies and gastroenterostomy
duodenal ulcer and 1 with a double vagotomy
gastrectomy.

43 CLINICAL STUDIES OF IRON ABSORPTION AFTER GASTRIC SURGERY. (Ger.)

Kuss,
(U. Bonn, Germany). Aerztl. Forsch. 20(3):
-126, 1966.

absorption of Fe was studied in 23 normal
sons, 22 patients with gastric carcinoma, 12
h gastric ulcer, 12 with duodenal ulcer, 4
es of cardiospasm, 2 with pyloric stenosis,
ith peptic ulcer of the jejunum after
lroth II gastrectomy, and in 1 case of
troenterostomy. Fe absorption was also
studied in 12 cases of esophagoantrostomy, 6 instances of esophagogastrostomy, 6 patients with Billroth I and 9 with Billroth II constructions, 6 having total gastrectomy with V-shaped esophagojejunostomy, 9 with complete gastrectomy replaced by the small intestine. Absorption of Fe was tested in single instances of gastric fornix carcinoma, penetrating ulcer of the lesser curvature, stomach body carcinoma, Billroth II reformed 2.5 yr. later as a Billroth II in a patient who had had peptic ulcer, another with stump gastritis original Billroth II reformed after 18 yr., and 1 patient with a Billroth II after resection for pyloric stenosis. The serum levels of Fe were obtained at 0, 2, 4, and 6 hr. before and after recovery from operation following a dose of 240 mg Ferro-Sanol p.o. Experiments on absorption of ferrous and ferric ions in intestinal loops in vivo and in vitro were also carried out. The normal fasting serum levels of Fe in man lie between 120-150 μg% and in women between 80-100 μg%. After the oral admin. of 240 mg of ferrous iron, the serum level rose by approximately 100 μg%. When the serum level is increased to 220-250 μg% in the course of 6 hr. this cannot be constructed as pathologic; a minimum increase of 50 mg% is to be expected with an oral dosage of 240 mg. The normal curves usually lay between these limits; 2 types of normal curves were observed, 1 with the highest serum level at 2 hr. after oral dosage and the other with the highest level at 4 hr. In general, the Fe serum level curves of all pathologic conditions studied were high or within the normal range prior to surgery; after surgery the serum levels were lower but still within the normal range. Oral admin. of ferrous iron showed no specific relation to the disease or the particular type of operation, considered singly or in terms of the av. Ferric iron was absorbed from loops and in vitro as readily, however, as ferrous iron. In an acid medium, absorption of ferric iron was less inhibited than the absorption of ferrous iron. The pH therefore has some effect upon absorption. Numerous factors both extra- and intracellular seem to determine absorption of iron among other substances; decreased metabolism, decreased bile secretion, reduction of absorptive surface, and atrophy of the mucosa all can decrease absorption.

7044 DIFFICULTY IN DIAGNOSIS OF MUCOSAL EROSIONS IN THE PYLORUS. (Ger.)

Szeleczky, G. (U. Debrecen, Hungary). Langenbeck. Arch. Klin. Chir. 317(1):14-21, 1967.

A report is presented of 2 cases with similar symptoms including cramp-like pains in the right upper gastric region radiating backwards. In 1 case stomach ulcer or tumor was suspected. Upon gastrotomy no lesions were found in the body of the stomach; the incision was continued into the pylorus; here ulcerations the size of linseed and multiple erosions the size of rice grains were discovered. The tunica propria of the mucosa was intensively infiltrated by plasma cells and lymphocytes; there was moderate subserous connective tissue proliferation in the regions of the erosions. The other case was diagnosed as polyposis of the stomach. Gastrotomy failed to reveal polyposis; extension of the incision into the pyloric region again revealed linseed-sized ulcerations and many small erosions all within the boundaries of the pylorus. In view of the long term symptoms experienced by these patients the lesions must either heal leaving no trace, or, after an interval, transform into a peptic ulcer. The circularly-located erosions, restricted to the pylorus and chiefly to the pyloric ring, cause the same difficulty as a duodenal ulcer: a delayed emptying of the pylorus (functional stenosis). Operations which are simple gastric sections are unsuccessful in this condition. The pyloric ring must be carefully examined, palpated and even transected; otherwise the erosions cannot be diagnosed. In view of the 2 cases outlined, it is suggested that the best surgical management of the disorder is vagotomy and pyloroplasty.

7045 RELATIONSHIP BETWEEN FINDINGS IN THE GASTRIC MUCOSA AND GASTRIC DISEASES AND SECRETION OF ABH-SUBSTANCES. (Ger.) Berg, G. (U. Erlangen-Nurnberg, Germany), H. Mayer, K. Heinkel and T. Schricker. Munchen. Med. Wschr. 109(8):401-406, 1967.

The relationship between the condition of the gastric mucosa, more specifically the degree of inflammation or atrophy, and also the distinct type of clinical disorder, as ulcer and carcinoma, and the blood groups (agglutinogens) including Rh of these individuals was investigated; also determined was the percentage of subjects who were secretors (salivary) of specific agglutinins. For the blood grouping direct typing was done; then the serum was tested for agglutinins with washed RBC of known groups. Agglutinogens A_2 (H), B, and O were discovered among those tested but not one instance of A_1 was found. The procedures used were carefully standardized. Those tested were grouped in 2 ways; 322 had biopsies taken of the gastric mucosa; among these were 101 normal subjects, 89 with moderate inflammation, 27 with severe inflammation, 29 with beginning atrophy, 63 with atrophy, and 13 with intestinal metaplasia; 78 did not undergo biopsies. On the basis of clinical diagnoses 60 individuals had healthy stomachs, 92 had duodenal ulcer, 78 gastric ulcer, 46 gastric carcinoma, 48 chronic bronchitis, 49 diabetes mellitus, and 27 with acute and chronic pancreatitis. Of the 400 subjects 313 or 78.25% were secretors and 87 or 21.75% were nonsecretors. On the basis of 322 cases 146 were Group A, 78.8% secretors; 38 Group B, 68.4% secretors; 15 Group AB, 80% secretors; and 123 Group O, 79.7% secretors. The distribution of those with biopsies in relation to the condition of the gastric mucosa and the international blood groups showed a close correlation between the actual number of subjects and their percentage in the group; thus among 89 with moderate inflammation of the mucosa, 45 (50.6%) were in Group A, 9 (10.1%) in Group B, 3 (3.3%) in Group AB, and 32 (36%) in Group O. No significant differences existed between condition of the gastric mucosa and the blood groups. Comparison of the percentages of secretors (67.4%) and nonsecretors (32.6%) in patients with duodenal ulcers to those in other gastric disorders or to the normal values (83 + 17%) demonstrates that these figures are significant. Only in this instance did such a difference appear in this investigation and the total number of cases may have been too small.

7046 GASTRIC RESECTION AND ALCOHOLISM. (Ger.) Reichmann, J. (Karl Marx U., Leipzig, Germany) and L. Pöcker. Z. Aerztl. Fortbild. (Jena) 61(9):489-493, 1967.

An inquiry was made into the relationship between gastric resection and alcoholism in 2 groups of persons, 1 group of 310 subjects with gastric resection, and the other group of 592 institutionalized alcoholics. Among the resected, 165 (53.2%) stated that they enjoyed alcohol as much as before surgery although their tolerance was not as great; 71 (22.9%) declared that they had not used alcoholic beverages before the operation but would do so now. Seven (2.26%) men had taken to drink in the past 2 yr. (their resections were about 3.5 yr. old) and were in difficulty with respect to work, families, or police. Five (1.6%, 3 men and 2 women) had been heavy drinkers before operation and continued to be so afterward; 14 (4.5%) were occasional drinkers with ulcers; 9 (2.9%) began to drink occasionally after resection; 14 (4.5%) others denied any consumption of alcohol. Among the 592 institutionalized alcoholics, 56 (9.5%) had undergone stomach resection for ulcer. The origin of the alcoholism cannot be the stomach resection in 40 of these 56 cases because their predilection for drink was patently greater at the time of the operation than afterward. Alcoholism is considered to be a disease process with a common beginning and a progressive course. The habituated person uses alcohol, known or unknown to himself, as a working, specific psychic drug. There is no causal relation between gastric resection and alcoholism or, at most, only an occasional relationship. Although drinking may have become more general in the resected group, except in a few cases the drinking was not excessive. On the other hand, the incidence of gastric resection among the alcoholics was too small (9.5%) for alcoholic excess to be the direct and sole cause of ulceration.

7047 THE COURSE OF CHRONIC GASTRITIS. (Ger.) Heinkel, K. (U. Erlangen, Germany), J. Pringot and N. Henning. Munchen. Med. Wschr. 109(14):763-767, 1967.

a total of 7123 patients examined, 360 were
osen for further study by biopsy over a period
at least 3 mo. In 66.6% the histological
ndings remained constant for periods of 1-3
In 10.7% an improvement in morphology
curred within 4 mo., and in 16% a deterioration
s observed. Morphologic changes were only
ghtly dependent upon the time interval be-
een examinations. Marked superficial
tritis and the beginning stage of atrophic
tritis were the most variable findings.
sons in the 40-49 yr. age group most
quently showed changes between the first and
ceeding examinations. Young people and the
erly showed greater stability in existing
ditions of the gastric mucosa. In only 2.5%
a change of 2 or more stages in diagnosis
erved. The diagnostic stages were: (1)
mal, (2) almost normal, (3) moderate super-
ial gastritis, (4) fully-developed superficial
tritis, (5) beginning of atrophic gastritis,
fully developed atrophic gastritis. Patients
h duodenal ulcers showed deterioration more
quently than patients with gastric ulcer.
rovement in troublesome upper abdominal
ptoms occurred in 64.5% of patients
eriencing them, but a corresponding change of
tric morphology did not necessarily occur;
phology and symptoms were not interdependent.
se investigations demonstrate the high
gnostic value of biopsies, not only in gross
ntification but also in fine differentiation.

8 THE RELATION BETWEEN AFFERENT LOOP
SYNDROME AND THE LENGTH OF THE LOOP IN
LROTH II WITH ANTECOLIC GASTROENTEROSTOMY.
r.) Reding, R. (Ernst Moritz Arndt U.,
ifswald, Germany), V. Puschmann and W. Senst.
tsch. Gesundh. 22(12):553-558, 1967.

roup of 255 patients who had undergone
tric resection and Billroth II construction
h antecolic gastroenterostomy during the last
r. were investigated. In the clinical and
oratory studies special emphasis was placed
n the afferent loops in the X-ray films.
ogether in 81 cases the afferent loop was
rt; 74 of these individuals were completely
e of untoward symptoms; in these 74 a reflux
sed covering of the mucosa or a rapid filling
the loop with contrast material occurred;
s was not considered pathological. On the
er hand, in the entire group were 13 with
afferent loop syndrome; based upon clinical
dence and X-ray demonstration of dilated,
erately to excessively-filled afferent loops,
iagnoses of Type I/II and 2 of Type III were
e; in 4 patients (Type IV) obstruction was
plete at the jejunogastral anastomosis
ween the seventh and eleventh postoperative
s. An enteroanastomosis was constructed at
eat surgery. There is a definite correlation
ween the length of the afferent loop in
ecolic gastroenterostomy and postoperative
orders. Only 1 patient of the 81 with short
afferent loops had a mild syndrome (Type I); 5% of all cases had this syndrome.

7049 CHANGES IN THE PATTERN OF LACTIC DEHYDROGENASE ISOENZYMES IN EXPERIMENTAL GASTRIC LESIONS. (Cz.) Procházka, B. (Charles U., Prague), J. Kohout, L. Korbová, V. Jirásek, V. Bárta and M. Procházková. Cas. Lek. Cesk. 105(49-50):1359-1364, 1966.

The total activity of LDH and the levels of 5 LDH isoenzymes (LDH 1, LDH 2, LDH 3, LDH 4, and LDH 5) in the mucosa of the fundus, in that of the pylorus, and muscularis propria of the stomach of normal Wistar rats, starving rats, and rats with experimental gastric lesions, induced by immobilization of starving animals, were compared. The gastric lesions (erosions and hemorrhages) were localized almost exclusively in the fundic mucosa. Supernate obtained after low speed centrifugation of the homogenized tissue was fractionated by agar gel electrophoresis to determine the activity of individual isoenzymes. Changes in the proportion of individual LDH isoenzymes were regarded as reflecting changes in the ratio of energy produced in the tissue by anaerobic glycolysis and oxidative processes (e.g., LDH 1 is predominant in tissue with aerobic, while LDH 5 in that with anaerobic glycolysis). The total LDH activity in fundic mucosa in the vicinity of erosions markedly decreased, while in other parts significantly increased, in comparison with corresponding tissue from control animals. On the other hand, differences were not observed between experimental and control rats in the total LDH activity of the pyloric mucosa, and of the muscle of the fundus or pylorus. The content of LDH 2, LDH 3, but especially of LDH 1, isoenzymes was decreased in the mucosa of the fundus in the vicinity of the lesions, while that of LDH 5 increased, when compared with the fundic mucosa of normal rats. This indicates that in the tissue in the vicinity of lesions a shift towards anaerobic glycolysis occurred. In the rest of the fundic mucosa of rats with gastric lesions the LDH 2 level was increased, whereas that of LDH 3 and LDH 4 decreased. In the pyloric mucosa of rats with gastric lesions the LDH 5 content increased, but the levels of LDH 1, LDH 2, LDH 3, and LDH 4 were decreased. The content of isoenzymes in the muscle of fundus or pylorus was not affected by induction of experimental gastric lesions. Starvation alone also did not affect the level of individual isoenzymes in the whole mucosa of the stomach.

7050 FREQUENCY OF GASTRITIS IN DISORDERS OF THE CARDIA AND ESOPHAGUS. (Ger.) Šetka, J. (Charles U., Prague), H. Dvořáková and B. Bednář. Wien. Z. Inn. Med. 48(2):80-82, 1967.

Thirty patients with incompetence of the terminal esophagus (insufficiency of the cardia) underwent simultaneous biopsies of the gastric mucosa and the esophagus, showed symptoms of a cardia-esophageal irritation for more than 2 yr., with or without a sliding hiatus hernia. These patients had no other gastrointestinal disorders. The diagnosis was established through an esophageal perfusion test, esophagoscopy, X-rays, X-ray cinematography, parietography, cholecysto- and cholangiography. All patients had been under a hygienic and dietetic regimen for at least a yr. The group presented a representative variety of the conditions disrupting the coordinated motility of the stomach. These patients were compared to 30 chronic, hospitalized alcoholics who at the time of the biopsies were in a stabilized condition, had not been treated with disulfiram, and had not recently had any alcohol. None of the alcoholics, as far as could be determined, had ever had any symptoms of a cardia-esophageal irritation. The av. age in both groups was 50 yr. Histologic examination of the biopsies revealed that only 16% of those with insufficiency of the cardia had a normal gastric mucosa; 84% had a chronic gastritis (64%, superficial gastritis, 20%, beginning atrophic gastritis). The simultaneous esophageal biopsies showed an incidence of esophagitis of only 10% among those with insufficiency of the cardia. Forty per cent of the alcoholics had gastritis; 60% had a normal gastric mucosa. In a group of 211 patients, gastritis occurred in 92% after gastric resection, in 100% of those with pernicious anemia.

7051 HCl PRODUCTION OF THE STOMACH AFTER BUTAZOLIDIN. (Ger.) Hemmati, A. (U. Bonn, Germany). Med. Welt 18(18):1140-1143, 1967.

Fasting normal persons (10 men and 10 women) underwent intragastric pH recording by means of the Heidelberg capsule. After the fasting determination, another recording was made during stimulation by caffeine or histamine; the capacity to form HCl was tested in cases of hyper-, normal and hypoacidity using the alkali test time. The subjects were treated for 7 days with 300 mg/day of butazolidin; on the eighth day the intragastric pH measurements were repeated. Ten other subjects underwent exactly the same routine except that a placebo was substituted for the butazolidin. Among the group of 20, 7 had hyperacidity, 5 normal acidity, 4 hypoacidity and 4 anacidity (histamine refractory). The av. pH before butazolidin was 3.77; after butazolidin, 3.71. Using alkali test time: before, 15.00, after 12.75 Free HCl was increased by butazolidin, but titratable acidity was decreased. There was no correlation between acidity and painful reactions to butazolidin. Of the group of 10 subjects, 2 had hyperacitity, 4 normal acidity, 3 hypoacidity, and 2 anacidity. The av. pH before the placebo was 4.380, after the placebo 4.385; alkali test time: before, 17.5; after, 17.8. The relatively small increase in acidity following butazolidin therapy cannot be the cause of severe gastric pain and ulceration.

7052 RESEARCH ON THE ACTION OF METACLOPRAMIDE IN THE STOMACH USING THE ENDORADI CAPSULE-"THE HEIDELBERG CAPSULE". (Ger.) Stillger, E. (U. Heidelberg, Germany). Med. Welt 18(21):1319-1320, 1967.

A "Heidelberg Capsule" was used to follow the action of the drug metaclopromide in the stomach of 12 patients; the capsule is an encapsulated transmitter fitted with the proper transducers; the pH in the range from 1-7 ± 0.5 is continuall transmitted for periods up to 90 min.; the mucin content of the gastric secretion, the bound acid and the acid-forming capacity as well as the motor activity of the stomach can be picked up and transmitted to a girdle antenna and direct-recording receiver. The fasting patient swallowed about 3 g of popcorn to stimulate stomach activity; the capsule attached to a filament of cat gut was then swallowed; the cat gut was taped to the corner of the mouth to prevent the capsule from passing into the small intestine. The pH curves of the 12 patients showed very large individual variations after i. inj. of the drug. However, stimulation of gastr peristalsis occurred 6 min. after i.v. inj. of 20 mg of metaclopramide, reached a max. in 14-2 min. and ceased in about 24 min. Tolerance by the fasting patients was very good without any apparent effect on acid secretion. The increase motility caused opening of the pylorus and reflu of the alkaline duodenal juice into the stomach. Metaclopramide is a distinctly useful adjunct i X-ray diagnosis of the gastrointestinal tract because of its stimulation of motor function. I is also a powerful antiemetic.

7053 NEW PHYSIOLOGIC AND ANATOMIC VIEWPOINT ON THE VAGAL INNERVATION OF STOMACH A ANTRUM WITH RESPECT TO GASTRIC SURGERY. (Ger.) Hart, W. (U. Munich, Germany). Z. Gastroent. 4(6):324-337, 1966.

Gastric acid secretion was studied in patients with Billroth II operations; some had complete bilateral vagotomy; others had the bilateral vag branches to the fundus and the body selectively severed, cutting also the intramural fibers fro these branches to the antrum, but leaving intac the antral ramus of the vagus nerve and a branc of the dorsal vagus which supplies the antrum; nerves form plexi in the antral wall. The total number of patients studied is not stated. The of the stomach contents was measured by an intra gastric glass electrode. The effects of 0.5 mg atropine, 10 ml 5% $NaHCO_3$ soln., p.o., histamin (stated only as 0.3 ml, s.c.), and 16 U i.v. insulin, alone and incombination, were tested upo the intragastric pH. Atropine increased the aci secretion in the patients with selective partial vagotomy by as much as 75% over the secretion stimulated by histamine alone. The effect was only observed during the simultaneous stimulati of the gastric secretion phase brought about by the alkalinization of the gastric contents with $NaHCO_3$. The vagus fibers to the antrum

parently inhibit the release of gastrin.
ropine, by blocking these fibers, causes re-
ase of gastrin, increasing acid secretion by
rietal cells. Atropine caused no change in
id secretion in patients with bilateral, total
gotomy. The increase in acidity in 20 normal
bjects av. 33% when atropine and histamine inj.
llowed the $NaHCO_3$ soln., p.o. as compared
trials without atropine. It is suggested
at the fundus and body of the stomach be
lectively vagotomized at proximal partial
section (30-40%) so that the antral rami of the
gus are retained to inhibit secretion of
strin, thus reducing gastric acidity.

54 THE DIAGNOSTIC ACCURACY OF GASTROSCOPY.
ANALYSIS AND COMPARISON OF ENDOSCOPIC
OPSY FINDINGS IN PATIENTS WITH GASTRIC
THOLOGY. (Ger.) Banaski, D. (Heidberg Hosp.,
mburg, Germany), P. Bünger and E. Seeberger.
nchen. Med. Wschr. 109(8):394-398, 1967.

e comparison of the 2 diagnostic methods,
stroscopy (using the fiberscope), and the
stologic examination of biopsies, was tested
using both methods simultaneously on 840
tients. The overall results showed that 83.5%
all gastritis cases diagnosed by the fiber-
ope were confirmed by biopsy. Conversely, 80%
all gastritis cases diagnosed by biopsy were
so diagnosed by gastroscopy. The comparison
chiefly made in terms of gastritis because
ner diseases were relatively rare in the group
840 patients; hypersecretory, hypermotility
nsitive cases were 2.7%; carcinoma, 2.4%; and
stric ulcers, 5.8%. The comparative scores
the 2 methods: Agreement, gastritis, 143
ses (antrum), 84 (border areas), 303 (fundus);
gastritis, 2 (antrum), 84 (border areas), 70
undus); total 605. Disagreement, 39 cases
ntrum), 19 (border areas), 177 (fundus); total
. The region where the 2 methods differ most
h respect to diagnosis of gastritis is the
ndus. The authors conclude that gastritis is
tter distinguished by the fiberscope although
y by a narrow margin.

15 ELECTRON MICROSCOPIC EXAMINATION OF
ASPIRATION BIOPSY SAMPLES OF THE STOMACH
AINED BEFORE AND AFTER STIMULATION WITH BETAZOL.
r.) El-Hamalawi, J. (Lubeck Acad. Med.,
many), U. Ritter and N. Dettmer. Z. Gastroent.
):13-19, 1967.

eries of 4-6 biopsies were taken before and
and 90 min. after i.m. inj. of 50 mg of
azole from 5 fasting normal subjects; the biopsy
sue was immediately fixed and prepared for
ctron microscopy; 10-min. portions of gastric
ce were obtained and vol., acid conc. and
al acid determined. All patients had a normal
retory vol. and normal acid production; samples
the biopsy tissues were prepared for light
roscopy; no pathological conditions were found.
the resting chief cells the endoplasmic
iculum consisted of a confluent system of
ute cavities, seen in the electron microscope
a system of more or less parallel membranes
which were found granules of ribonucleic acid;
se granules or ribosomes in conjunction with
apparatus of the endoplasmic reticulum were
olved with the maintenance metabolism of
tein and the synthesis of pepsinogen. The
d-producing parietal cells contained a great
ber of mitochondria. The cytoplasm also
tained a large number of fluid-filled vesicles
reas the endoplasmic reticulum was not promi-
t, so that the electron microscopic pictures
the 2 types of cells were clearly different.
er max. secretory stimulation, the ultra-
ucture of the chief cells and the parietal
ls differed markedly from that of these cells
rest. The endoplasmic reticulum of the chief
ls completely disappeared; this occurred
oughout all the preparations of stimulated
sues. The thickness and general size of the
osomes decreased; all lysosomes surrounded
membranes seemed to have a clearer ground
ucture showing, however, a very dense central
nule which is seldom seen in the resting cell.
er stimulation, lysosomal material was
gregated near the glandular lumen; later
osomes were found in the lumen where they seemed
dissolve and liberate the contained enzyme.
egularly distributed granules of the size of
osomes were seen in the cytoplasm. The
mulated parietal cells showed sac-like
tuberances toward the glandular lumen into
ch the canaliculi arising from the confluent
icles emptied; the size of the single vesicles
not increase during stimulation; the mito-
ndria were arranged in the cell periphery in
se relation to the vesicular-canalicular
uctures. Microvilli were larger and more
erous in active cells.

16 THE X-RAY EXAMINATION OF THE SMALL
INTESTINE TREATED WITH METACLOPRAMIDE.
er.) Nägele, E. (U. Giessen, Germany). Fortschr.
entgenstr. 106(3):441-448, 1967.

The author made 60 X-ray examinations of the small intestine; some patients had normal digestive tracts, the others had suffered digestive tract diseases such as hiatal hernia, gastric or duodenal ulcer, gastric carcinoma, gastric resection. After Billroth II and diverticula of the jejunum and ileum, activity of the compound was the same in healthy and diseased digestive tracts. The dosage varied from 5-30 mg. In 39 of 50 cases, gastric tonus was increased and in 26, definite strengthening of peristalsis occurred. Emptying time of the stomach was decreased in 17 instances to less than 30 min. Better filling of the duodenum occurred in 22 subjects; duodenal peristalsis was not diminished with increased filling; it was, in fact, strengthened in 29 cases. The mucosal relief of the duodenum remained normal. The most striking effect on the digestive tract was the increased peristalsis in the jejumun and ileum recorded in 44 of 50 subjects. This was observed in all 38 cases receiving doses of 20 mg or more; the peristalsis was coordinated, speeding the transport of the small intestinal contents so that in 36 cases the cecum was filled in 30-60 min. This filling occurred in 87% of those receiving 20 mg or more. In spite of the rapidity of intestinal passage there was no diarrhea. X-ray delineation everywhere was of high order.

7117 CHAGASIC DUODENOPATHY. (Por.) De Britto Costa, R. (U. Sao Paulo, Brazil) and F. Gomes de Alcantara. Rev. Brasil Med. 23(3): 158-160, 1966.

A quantitative study of the intramural autonomic plexuses of the first portion of the human duodenum is presented. There was a 50% reduction in the number of ganglionic cells in both Auerbach's and Meissner's plexuses in patients with Chagas' disease. These results are in agreement with other reports obtained at different levels of the duodenum in patients with Chagas' disease. Twenty duodena were studied at autopsy (10 from chagasic cadavers and 10 from non chagasic cadavers). A 50% reduction in the number of ganglionic cells in both plexuses was found, and this morphological change could correspond to various physiological changes. Age ranged from 6-55 yr. in the non chagasic group (6 males, 4 females). The mean count for Auerbach's plexus was 1,432, and for Meissner's plexus it was 1,139. In the chagasic group the age ranged from 20-67 yr. (5 females, 5 males). The mean count for Auerbach's plexus was 763, and it was 564 for Meissner's plexus.

7118 CHAGASIC JEJUNOPATHY. (Por.) Gomes de Alcantara, F. (U. Sao Paulo, Brazil) and R. De Britto Costa. Rev. Brasil. Med. 23(5): 316-317, 1966.

The intramural autonomic plexuses of the human jejunum (first loop, taken from the middle of the loop) were studied in autopsy specimens obtained from 10 subjects with and 10 without Chagas' disease. Serial specimens fixed with formol were used. In specimens from patients with Chagas' disease, the mean number of ganglionic cells in Auerbach's plexus was reduced from 987-664 (= 33%); the mean number of ganglionic cells in Meissner's plexus was reduced from 2053-1331 (= 36%). These results were in accordance with those obtained at other levels of the digestive tract.

7119

ASSESSMENT OF VASCULAR INTEGRITY OF INTESTINAL SEGMENTS BY DYE INJECTION.

(E.) Kwong, K. H. (U. Colorado Med. Ctr., Denver), R. E. Fraser and B. C. Paton. Brit. J. Surg. 54(2):144-146, 1967.

After midline incision, a 20-30-cm segment of pylorus (5 dogs) or right colon (5) (Group 1), supplied by at least 3 branches of the jejunal or ileocecal arteries, was exposed. At 1 end of the segment, the arteries were ligated where they joined the collateral arcade; the intestine was divided and anastomosed, with a single layer of interrupted silk sutures, at a point where the blood supply was intact on 1 side only; at the other end, the intestine was divided and re-anastomosed at a point where blood supply was intact on both sides. Alpha zurine 2G dye was inj. (20 mg/kg) into a peripheral vein. The entire intestinal tract was uniformly stained green, except for a 7.5 cm segment not stained at 10-15 sec. and 2.5-5 cm segment patchily stained at 25-30 sec. The dye did not diffuse across the anastomosis between ischemic and normal intestine. The 2-poorly stained segments were marked with stitches, the intestine returned to the abdomen, dogs sacrificed and autopsied at 24-48 hr. after operation. In Group 2 (12) a 30-35-cm loop of jejunum, with a good arcade, had 1 or 2 jejunal vessels ligated at 1 end and was divided at this point; 20 mg/kg dye was inj. i.v. The intestine stained immediately, with the degree of staining varying. The ischemic end of the intestine was left alone or resected: in 4, anastomosis was performed in an area of patchy staining; in 4, in an area without dye; in 4, in an area of complete staining. Abdomens were closed, dogs killed as above. In Group 1, all the control anastomoses with an intact blood supply were intact. Anastomoses made with non-stained intestine all broke down, and suture-marked ischemic segments became black and necrotic. Patchily stained segments were all viable, although they appeared more congested than normal intestine and had petechial hemorrhages on the serosal surface. In Group 2, all anastomoses with uniformly stained intestine remained intact. Three with patchily stained intestine remained intact, 1 broke down. All 4 with non-stained intestine broke down, with sloughing of ischemic segment. The use of alpha zurine 2G dye to differentiate between normal and ischemic intestine is recommended in intestinal transplants.

7120

FREEZING AND PRESERVATION OF THE INTESTINE OF THE RAT FOR LONG PERIODS AT THE TEMPERATURES OF LIQUID NITROGEN. (Fr.)

Eygonnet, J. P. (Julliard Ctr., Clamart, France) Agressologie 8(1):83-87, 1967.

Adult rats (260-480 g) were killed by ether or bleeding and the duodenum or jejuno-ileum excise and placed in Tyrode's soln. at 37.5°C; the intestinal segments were then plunged into a 10% by vol. soln. of dimethylsulfoxide in Tyrode's which had been maintained at 37.5°C. The freezing was done after variable periods of incubation in the sulfoxide fluid (10, 20, 30, and 45 min.) according to 2 methods. Slow method: The segment was placed within the finge of a surgical glove; the segment was frozen at 80°C in the presence of 3 ml of soln. This temperature was obtained in a freon refrigerator the final temperature was -64°C. The rapidity of the temperature drop was 1°C/min. The ultrarapid method: The intestinal segment was frozen in a few sec. by direct immersion in a bath of liquid nitrogen. The defrosting was also done by 2 different technics. Semirapid defrosting: The tissue which had been slowly frozen was placed, still in the finger of the glove, in a water bath at 45°C. The duration of the storage at -64°C should not exceed 24 hr. Ultrarapid defrosting: The tissues rapidly frozen were maintained in liquid nitrogen or in the vapors from liquid nitrogen at -160°C for variable periods 1 hr.-8 wk. The defrosting was done in less than a min. The piece of intestine was placed in 100 ml of Tyrode's soln. in a thermostatted water bath. Sometimes 0.25 or 0.50 mg of $CuSO_4$ or 2-3 mg $BaCl_2$ were required to stimula the tissue. A latent period of 15-20 min. occurr before the tissue began automatic rhythmicity.

7121

ILEUS CAUSED BY ACENOCOUMARIN. (Dut.)

Deboer, H. H. M. (South Hosp., Rotterda Netherlands). Nederl. T. Geneesk. 111(15):675-678, 1967.

Four cases are reported of vascular complications arising from anticoagulant therapy using acenocoumarin for periods from 12 days-2 yr. for arteriosclerotic changes in leg arteries, prophylaxis after operation, thromboses, and heart infarction with atrial fibrillation; 2 cases were treated by surgery following obstruction in the jejunum and ileum in 1 and obstruction of the jejunum in the other; 2 cases, treated conservatively, had apparent obstruction of the small intestine. Prothrombin time was 60 sec. in 1 patient and more than 2 min. in the other 3; hemoglobin was 6.6 and 8 g% in 2 who had hematuria, and 13 and 16 g% in 2 who had s.c. hepatomas. All received vitamin K_1; 2 had blood transfusions, 1 plasma transfusion, and 1 rheomacrodextran and blood transfusion. In the small intestines of the operated patients, bleeding had occurred into the submucosa and in the subserosa. Characteristic symptoms were pain in

umbilical region, vomiting and distention of
abdomen. Recoveries were uneventful.

2 THE INFLUENCE OF GLUCOCORTICOIDS ON
INTESTINAL MUCOSAL HEXOSEMONOPHOSPHATE
NT ENZYMES IN THE RAT. (E.) Pfeiffer, C. J.
:. Aeronaut. Space Admin., Moffett Field,
f.) and P. J. Muller. Arch. Int. Pharmacodyn.
2):258-272, 1967.

nal intact or healthy, bilaterally adrenalecto-
ed-hypophysectomized male Sprague-Dawley rats
given s.c. inj. of 4, 12 or 36 mg of hydro-
tisone acetate or corticosterone acetate/kg
wt./day for 3 days. At necropsy, adrenal
nds, testes and thymus glands were removed
weighed; the proximal 12-inch portion of
unum was also removed. As a means of estima-
g hexosemonophosphate shunt activity, glucose-
hosphate dehydrogenase and 6-phosphogluconate
ydrogenase activity were assayed in jejunal
ogenates of control and corticoid-treated rats
spectrophotometric determination of reduced
otinamide adenine dinucleotide phosphate
nation. Both steroids inhibited body wt. gain
ng/kg) or induced a wt. loss (36 mg/kg);
rocortisone was approx. twice as potent with
ard to this toxic effect in intact rats and
it was more potent in producing wt. reduc-
n in adrenalectomized-hypophysectomized rats.
ever, the highest dose of either glucocorticoid
in. to either group of rats did not induce a
loss comparable to that caused by 3 days of
ting. Both steroids, especially hydrocortisone,
sed a reduction of absolute and relative
enal wt., absolute testicular wt. and an
olution of the thymus gland. Hydrocortisone
uced a significant inhibitory, log-dose (4-36
kg/day; 3 days) response in both mucosal
ymes in both groups of rats. Similar dose
els of corticosterone also inhibited jejunal,
osal glucose-6-phosphate dehydrogenase and
hosphogluconate dehydrogenase in both groups
rats; in intact rats, the highest dose of
ticosterone used (36 mg/kg) completely in-
ivated both enzymes. In adrenalectomized-
ophysectomized rats, the intermediate dose
mg/kg) gave less suppression than the lowest
e (4 mg/kg). Hydrocortisone was more active
stress-related changes in body, adrenal, thymic
testicular wt. It is suggested that mucosal
ceptibility to glucocorticoids may be related to
aired carbohydrate metabolism in the intestinal
osemonophosphate shunt.

3 CHANGES IN INTERNAL ENVIRONMENT IN
INTESTINAL STRANGULATION AND ITS
ATMENT. (Sp.) Silva, C. (Fac. Med., Montevideo,
guay). An. Fac. Med. Montev. 50(3/4):321-
, 1966.

eview of pre- and postoperative treatment of
ients with intestinal strangulation emphasizes
extremely high fluid loss and loss of
ctrolytes, together with replacement technics.
Three illustrative case histories are cited. The review is supplemented by report of the induction of an experimentally strangulated loop in 8 dogs with survival times ranging from 10-37 hr. Fluid losses at the level of the strangulated loop ranged from 28.7-64.8% (mean = 48.6%) total plasma vol. Among 81 patients who were hospitalized for strangulation during an 18-yr. period, the overall mortality rate was 24.6%. However, among 27 of 81 in whom irreversible lesions (e.g., hemorrhagic infarct) had occurred, necessitating resection, mortality rate was 58%. There was no significant sex difference, but age appeared to be a factor in survival. Although only 45 of 81 (55%) in the patient group as a whole were over 60 yr. of age, 15 of 20 (75%) of the decreased were over 60.

7124 CAUSE AND TREATMENT OF DIARRHEA FOLLOWING RESECTION OF THE SMALL INTESTINE. (E.) LeVeen, H. H. (VA Hosp., Brooklyn, N. Y.), B. Borek, D. R. Axelrod and A. Johnson. Surg. Gynec. Obstet. 124(4):766-770, 1967.

A bypass of the small intestine was created in 4 obese patients by anastomosing the end of the proximal portion of the jejunum to the side of the terminal portion of the ileum, creating a loop which was as short as possible; less than 18 inches of small intestine remained in all patients. A similar resection was performed on 1 patient for mesenteric occlusion. Two ounces of castor oil (a triglyceride of ricinoleic acid, the latter differing from oleic acid only by the presence of an hydroxyl group on carbon number 12) were admin. to normal subjects; almost all of it appeared in the stool as free ricinoleic acid or its soap and less than 20% remained in the form of neutral fat. In a 3-day period, 92 g/day of neutral fat were fed to patients both before and after bypass, and the stool was analyzed. Preoperatively, almost all of the fat was absorbed; postoperatively, the fat was almost completely excreted, but as fatty acid or soap rather than neutral fat. A similarity was found to exist between normals who excreted ricinoleate after ingestion of castor oil, and those with a bypass who excreted fatty acids and soaps after ingestion of neutral fats. The chemical cause of diarrhea was therefore postulated to be failure to absorb fatty acids during fat digestion. When 20.5 g of $CaCO_3$ were simultaneously admin. with castor oil, 4 of 5 normal subjects had solid stools while the fifth had a pasty stool without diarrhea. Admin. of as much as 20 g of $CaCO_3$ to patients with an intestinal bypass rendered their stools pasty or solid, eliminating explosive excoriating diarrhea. It is concluded that precipitation of fatty acids with $CaCO_3$ is an important part of management after bypass or resection of the small intestine.

7125 TUMORS OF THE SMALL INTESTINE. REPORT OF 65 CASES. (Por.) Rosenberg, D.

(U. Sao Paulo, Brazil), J. Pan Chacon, P. A. J. Faria, F. de Camargo Vianna, A. M. Cardoso de Almeida, J. A. de Mello Saraiva. Rev. Ass. Med. Brasil. 12(3):111-118, 1966.

Among 65 patients with tumors of the small intestine, 52 had malignant, 13 had benign tumors. Diagnosis, established by surgery, could not be confirmed by X-ray in one-half to two-thirds the patient group. There were no significant sex differences with respect to the frequency of incidence of either type of tumor. Duodenal tumors included 3 carcinomas, 1 sarcoma, 2 benign; comparable tabulations for the jejunum were 5, 6 and 5, resp.; for the ileum they were 5, 14 and 1, resp.; for patients in whom the segment of the small intestine was not defined they were 4, 12 and 5, resp. Also seen were 2 carcinoid tumors of the small intestine. Sarcomas and benign tumors showed an equal frequency of incidence in patients below and above 30 yr. of age. There were no carcinomas in patients under 30. The most frequent presenting symptoms were those of partial or total obstruction. Results of surgery were good in the presence of benign tumors, poor in the presence of malignancies.

7158 NEWLY DETECTED PULMONARY TUBERCULOSIS AND PEPTIC ULCER.

(Cz.) Musil, J. (Palacky U., Olomouc, Czechoslovakia). Rozhl. Tuberk. 27(1):21-23, 1967.

Of 1496 patients with newly detected, active pulmonary tuberculosis, admitted to the University Hospital in Olomouc during 1954-1965, 162 presented with gastroduodenal ulcer. Although the absolute number of persons admitted with tuberculosis decreased gradually during these 12 years, the porportion of those with ulcer complication increased from about 6 to 18%. The incidence of tuberculosis in persons with peptic ulcer is about 9 times higher than in the whole population of Czechoslovakia. The time interval between the appearance of the symptoms of the ulcer and those of tuberculosis was 10-11 yr., regardless of whether the ulcer was removed by surgery or not. The authors recommend improved preventive measures for early detection of tuberculosis in the fraction of population (about 2%) suffering from peptic ulcer.

7159 ACTION OF SUPERANABOLON R SPOFA (NANDROLONPHENYLPROPIONATE) ON THE DEVELOPMENT OF EXPERIMENTAL GASTRIC LESIONS.

(Cz.) Korbová, L. (Charles U., Prague), Z. Pokorný, J. Kohout and M. Procházková. Cas. Lek. Cesk. 105(49-50):1349-1352, 1966.

The effect of Superanabolon (beta-phenylpropionate-19-nortestosterone) on the development of experimental gastric lesions in Wistar rats, induced by immobilization of the animals, was investigated. In one set of experiments groups of rats were inoc. i.m. 24 and 0 hr. before immobilization by 0.5, 5, 25, and 50 mg of Superanabolon, resp., per kg wt. and daily. In another series, Superanabolon was admin. in amounts of 5 and 25 mg, resp., per day and kg wt. during the last 6 days before immobilization. In control groups the animals were either immobilized without treatment or without immobilization treated with Superanabolon in similar ways as in experimental groups. During immobilization the rats were not fed, but they received s.c. 5 ml of physiological saline. After 22 hr. of immobilization the rats were killed, their stomachs removed, and the lesions of the gastric mucosa evaluated. In rats which received 0.5 or 5 mg/kg of Superanabolon during the 2 days before immobilization, the number and the size of lesions was reduced by 43 and 23%, resp. However, when higher doses of Superanabolon (25 or 50 mg/kg wt. and day) were admin. under similar conditions, the extent of the damage to the gastric mucosa was by 29% higher than in untreated, immobilized rats. Similarly, the number and size of lesions increased by 60%, when the animals received 5 or 25 mg/kg of Superanabolon during the last 6 days before immobilization. Rats which were not immobilized, but treated with comparable doses of Superanabolo did not develop gastric lesions.

7160 HYPERSENSITIVITY OF THE GASTRIC MUCOSA OF THE RAT TO REPEATED ADMINISTRATION OF BISMUTH SUBNITRATE.

(Fr.) Huyen, V. N. (Joullie Res. Lab. Serv., Hauts-de-Seine, France) and S. Garcet. Sem. Ther. 43(1):34-37, 1967.

In rats treated for 10 days with bismuth subnitra (total 1 g/kg), no macroscopic changes were noted in the prepyloric area of the stomach, but histological studies showed mucosal abrasion with exposure of the glandular elements, epithelial desquamation with cellular lysis, inflammatory edema and signs of hypersecretion of mucus. In rabbits treated with the same dose of bismuth subnitrate, no gross or microscopic changes were noted in the stomach; it is concluded that the rabbit stomach is similar to the human stomach in this respect.

7161 THE FREQUENCY OF DIFFERENT BLOOD GROUPS IN GASTRODUODENAL ULCER.

(Rus.) Gheller, L. I. (Khabarovsk Med. Inst., USSR), E. A. Svetacheva and E. P. Il'enko. Ter. Arkh. 38(11):35-36, 1966.

The frequency of various blood groups was analyze in 2021 patients with gastroduodenal ulcer and compared with data from 3906 healthy donors. The was no statistically significant difference found either in men or in women with gastric and duodenal localization of the ulcer. It is concluded that data in the literature on the relativ predominance of blood group 0 in gastroduodenal ulcer is not justified.

7162 CURLING'S ULCER.

(Fr.) Nasilowski, W. S. (Inst. Hematol., Warsaw, Poland). Acta Chir. Belg. 65(7):772-773, 1966.

Over a period of 14 yr. 981 adult patients were hospitalized for treatment of burns of whom 110 died as a consequence; autopsy of 95 cases revealed the presence of gastroduodenal ulcers (Curling's ulcers) varying between 5-18 mm in 6 cases (3 males and 3 females; ages 20-71 yr.). The ulcer was located in the duodenum in 5 cases and in the ventricle in 1 case. The ulceration was multiple in 2 cases and complicated by fatal massive hemorrhage in 1 case and by diffuse peritoneal perforation in 2 cases. All cases involved third- or fourth-degree burns which were due to fire in 5 cases and electricity in 1. In only one case (aside from those with obvious complications) was the ulcer diagnosed. In fact, 2 cases were receiving ACTH treatment for the burns which probably enhanced the development of the Curling's ulcer, as histologically the ulcers resembled acute ulcers often seen with corticosteroid treatment: lack of a transition zone between the oozing substance and the mucosa, lack

peripheral induration and similarity in
e. Curling's ulcers might appear after the
st several wk. and this possibility must
ays be considered, especially when treatment
h ACTH or corticoids is decided upon.

3 HEMORRHAGES·OF CIRRHOTICS WITH ULCERS.
(Fr.) Dupuy, R. (Beaujon Hosp.,
is) and J. Marteau. Rev. Prat. 17(6):715-725,
7.

-to-side portacaval anastomoses were
formed at the same time as 2/3 gastrectomies
4 cirrhotic patients suffering from bleeding
ers. Of these 4 cases, 3 were considered
cesses, 1 surviving after 2 mo., another
er a yr. and, the third, after 2.5 yr. The
rth patient died 2 mo. after the intervention,
bably because of transfusion hepatitis. Two
er failures are mentioned upon whom double,
plete vagotomies, as well as the above-
tioned surgery were performed. However, these
es were complicated by ascites and encephalo-
hic difficulties. Numerous complications of
combined pathology of cirrhosis and ulcers
discussed in detail: of 9 cirrhotic patients
n with ulcers, only 2 presented a typical
er syndrome. Two others presented with pseudo-
iary symptomatology, two with pseudogastric
rtburn and three were without symptoms. Yet,
tric ulcer is the second most common cause of
th among cirrhotic patients. Prognosis was
rer in those patients with jaundice, ascites,
betes, anemia, hyposiderinemia and multiple
ers. Only when portal hypertension was not
sent and the ulcer condition seemed mild, was
ical treatment effective, which included
muth, aluminum gels, polysilane, i.v. vitamin
nd protein therapy.

4 GASTRIC ULCER AND ANTRAL BORDER. (E.)
Ruding, R. Surgery 61(4):495-497,
7.

exact location of the gastric ulcer was
ermined in a sequence of 80 resected specimens;
were located in the antrum, 34 on the boundary
ween fundus and antrum. None were found in the
dus gland region. It is thought that a fairly
ge percentage of the 46 antral ulcers were
uated near the antral border. It is further
othesized that ulcer development is dependent
n the coincidence of 2 factors, e.g., exposure
the mucosa to HCl and its sensitivity to this
d. The sequence of sensitivities to HCl by
cosa is thought to be highest in esophagus,
lowed in order by duodenum, antrum and fundus
ere sensitivity is negligible). The significance
these findings is discussed, and it is stated
t antral resection in the treatment of ulcers
olves removal of that part of the stomach that
duces gastrin as well as the portion most
ely to produce ulcers.

7165 THE CHANGE OF BOWEL HABITS FOLLOWING VAGOTOMY AND PYLOROPLASTY. (E.)
Barnes, A. D. (U. Birmingham, England) and J. A. Williams. Brit. J. Surg. 54(3):218-220, 1967.

Subjects were 92 consecutive duodenal ulcer patients treated by truncal vagotomy and Weinberg pyloroplasty over 4 yr., with 1.5-4.5 yr. follow-up. Thirty-one showed no change in bowel habits. Of the 61 who changed, 46 were pleased that they were cured of constipation; 11 displeased; 4 made no reply. Of the 11, 1 claimed increased constipation, 10 troublesome diarrhea. In all, 62 reported diarrhea at some time during follow-up; an av. of 25% reported diarrhea during each postoperative yr. Early diarrhea was more often associated with gastric retention than with later bowel disturbance. All 10 with troublesome diarrhea had first symptoms in first yr., 7 in the first mo. To these were added 7 from other surgeons with the same symptoms, and all were studied for 3 mo. Patients were given 1 of 3 tablets to be taken 3 times daily for 3 days for diarrhea: codeine phosphate 15 mg; diphenoxylate HCl 5 mg and atropine sulfate 0.05 mg; an inert placebo. During study, only 6 of 10 had diarrhea. Only 2 ever had more than 3 stools daily (1 of whom had chronic pancreatitis preoperatively). Four had troublesome diarrhea, but never more than 3 stools daily. These received no benefit from codeine or diphenoxylate and atropine, although those who pass more than 3 stools daily are benefited equally by either. Placebo subjects continued in a course characteristic of untreated, severe, postvagotomy diarrhea.

7166 VAGOTOMY IN THE RAT. A STUDY OF ITS EFFECTS ON STOMACH AND SMALL INTESTINE.
(E.) Ellis, H. (Westminster Hosp., London) and J. Pryse-Davies. Brit. J. Exp. Path. 48(2):136-141, 1967.

Studies on abdominal vagotomy, uncomplicated by gastric drainage, in adult and immature albino male Wistar rats are reported. Morphological and histological observations of stomachs of 50 adults were made 12-32 wk. after vagotomy. Of these 13 (26%) had stomachs of normal size, mean wt. with contents 8.8 g; 20 (40%) had dilated stomachs but with normal mucosal appearance, mean wt. of 25 g; 17 (=34%) had dilated stomachs showing gastric ulceration, mean wt. 26.5 g. Cineradioautography and microdissection supported the hypothesis that nondilated stomachs probably represented incomplete vagotomy. Ulcers of all grades were observed, were usually solitary, and occurred in the lesser curvature, never the rumen or antrum. There was no relation between the histological extent of the ulceration and the time elapsed since vagotomy (1-32 wk.). Including 10 controls, 24 (=40%) of 60 rats, in whom vagotomy appeared to be complete, developed gastric ulceration. None of the animals with undilated stomach showed dilatation of the esophagus, whereas 3 with dilated stomachs did. No significant differences were noticed in small intestines of vagotomized rats from those of controls, who were only laparotomized. Vagotomy had no effect on wt. gain or on general growth of the rats. Studies on distribution of enzymes in the stomach and small intestine are also reported.

7167 WEIGHT BEHAVIOUR AFTER OPERATION FOR DUODENAL ULCER. (E.)

Small, W. P. (Western Gen. Hosp., Edinburgh, Scotland), C. W. A. Falconer, A. N. Smith and J. Bruce. J. Roy. Coll. Surg. Edinb. 12(2):133-138, 1967.

A study is reported on the wt. behavior of 538 duodenal ulcer patients treated more than 5 yr. previously by either Polya gastrectomy (subtotal resection with removal of 2/3 of stomach) or vagotomy (subdiaphragmatic and unselective) and gastroenterostomy (no-loop, isoperistaltic, retrocolic anastomosis). At the time of this study, 29% of the patients were thin (defined after Kemsley), while 49% were thin at the time of operation and 72% gained wt. after operation, so that in this group operation was usually followed by a wt. gain. Since the patient for gastric surgery already has an ulcer, he is not healthy and his wt. at this time is not valid. Comparison should be made with wt. before illness. Postoperative wt. gain usually did not compensate for preoperative loss. In most patients, operation led to an enhanced state of nourishment, but not restoration of lost wt. The constitutionally thin patient should not be denied surgical treatment solely because he is thin. The choice of operative procedure need not be predicated in terms of wt. response as there is no significant difference.

7168 STOMACH DRAINAGE AFTER VAGOTOMY AND PYLOROPLASTY. (E.)

Barnes, A. D. (Gen. Hosp., Birmingham, England) and J. A. Williams. Amer. J. Surg. 113(4):494-497, 1967.

In 108 consecutive patients with duodenal ulcer treated with truncal vagotomy and pyloroplasty even if the duodenum was scarred, edematous, or the site of recent perforation, the incidence of postoperative gastric retention in 73 patients without stenosis was 10%. Of 55 patients with ulceration of 10-45 yr. duration, 5 had retention. Of 49 with less than 10 yr. history of ulceration, 6 had postoperative ulceration. The age range of the series was 16-78 yr. The age range of the patients with retention was 21-63 yr. There was no sex variation. The incidence of retention decreased during the 4 yr. of the study. When the series was begun, none of the surgeons involved had much experience with vagotomy and pyloroplasty. During the final 2 yr. of the study the only patient having prolonged retention was operated on by a surgeon performing his first pyloroplasty. Of patients with nasogastric drainage 71% had infection of chest (signs in chest with temperatures above 99° F) or wounc Of those with gastrostomy, 96% experienced infection, and 43% with no tube had infection. The high incidence in the second group was believed due to the selection of this procedure for patients with chronic bronchitis.

7169 GASTRODUODENAL ULCER AND PERIPHERAL ARTERIOPATHIES: CLINICAL AND PATHOGENETIC STATISTICAL FINDINGS. (It.)

Tajana, A. (U. Milan, Italy) and B. Doldi S. Arch. Ital. Chir. 92(5):676-685, 1966.

Among a group of patients with arterial obstruct 58 of 513 were also found to be suffering from gastric or duodenal ulcer. The male:female rati among the ulcer patients was 57:1; among all tho with arterial obstruction, it was approx. 19:1. There was no apparent relationship between the site of obstruction and the occurrence of ulcer. Gastric symptoms had appeared first, in all case Among 9 of 58, aged less than 40 yr., the mean interval was 7 yr. (range = 2-17 yr.); among 33 of 58, aged 40-60 yr., the mean interval was 12 yr. (range = 1-34 yr.); among 16 of 58, aged more than 60 yr., the mean interval was 16 yr. (range = 1-40 yr.).

7170 EXPERIMENTAL ULCEROGENIC ACTIVITY OF VARIOUS CORTICOSTEROIDS. (It.)

Tursi, A. (U. Bari, Italy), V. Liso and N. V. Grimaldi. Reumatismo 18(6):517-532, 1966.

A mean ulcer index (representing the mean number of ulcers induced, the av. degree of severity, and the percentage incidence of ulceration) was employed to compare 24 groups of female white rats, weighing approx. 150 g at the start of the experiment and subjected to various courses of treatment with corticosteroids as follows (all for 5 days): dexamethasone (2 mg/day p.o.) = 19. triamcinolone (8 mg/day, p.o.) = 17.8; ACTH (10 mg/day, i.m.) = 16.1; prednisone (10 mg/day, p.o.) = 14.8; prednisone with gastric buffer (same dose) = 14.2; 16-β-methyl prednisolone (8 mg/day, p.o.) = 14.1; 6-α-methyl prednisolone (10 mg/day x 5, p.o.) = 14.0; depot ACTH (10 mg/ day, i.m.) = 13.9; 6-α-methyl prednisolone acetat (10 mg/day, i.m.) = 12.9; paramethasone (4 mg/day, p.o.) = 11.1; 6-α-fluoroprednisolone (4 mg/day, p.o.) = 11.0; prednisolone (10 mg/day, i.m.) = 9.0. When the same drugs were admin. for the same length of time but at 10% the dose levels indicated, comparable tabulations were 12.1, 10.8, 8.2, 8.0, 8.2, 8.4, 8.3, 7.9, 7.2, 6.2, 5.8 and 5.1, resp. In a corollary study, rats receiving prednisone, 10 mg/day for 5 days, p.o., had a mean ulcer index of 12.5, while rats receiving prednisolone in the same dosage, i.m., had an index of 8.5. It is concluded that parenteral admin. of corticosteroids tends to lessen their ulcerogenic potential and that this tendency is most marked in those which have a fluorine atom in the C_6 position. It is noted

the ulcers induced in rats differed from
n peptic ulcers in a number of ways, including
absence of inflammatory and regenerative-
tive processes.

GEL-INFILTRATION PURIFICATION OF A
PROTEIN FACTOR (UROGASTRONE) FOUND IN
URINE OF PREGNANT WOMEN AND INHIBITS GASTRIC
ETION AND GASTRIC ULCERATION. (It.) Lugaro,
U. Milan, Italy). Farmaco (Prat.) 21(11):
595, 1966.

thod is described for purifying urogastrone
iltration of Sephadex gels, yielding a
ogically active, final fraction (Ug G-100)
n represents approx. one-third the wt. of
original material but retains approx. 100%
oth its antisecretory and antiulcerative
vities. The fraction has no antigonadotropic
vity, whose presence in previous endproducts
ow thought to have been due to impurities,
no activity similar to that of the follicular
ulating hormone.

CLINICAL AND STATISTICAL CONSIDERATIONS
IN THE TREATMENT OF PERFORATIONS OF
RODUODENAL ULCERS. (It.) Ciuffini, F.
Perugia, Italy) and B. Tristaino. Acta Chir.
. 22(5):443-458, 1966.

g 58 men and 1 woman, presenting with
orated gastroduodenal ulcers, the age range
16-85 yr. (mean = 38 yr.), with 16.9% of
cases occurring in the third decade of life,
% in the fourth, 13.59% in the fifth and
5% and 10.1% in the sixth and seventh, resp.
half the group gave a history of typical
roduodenal ulcer symptoms. In 44 of 58, a
le ulcer was found in the first segment of
duodenum; in 5, two ulcerations were found
e; in 1, a single ulcer was found in the
nd segment; in 9, the ulcer was gastric.
of the patients were bleeding. In 3 of 59,
ery was confined to repair of the perfora-
in 1 of 3, because of cardiac and
ratory insufficiencies; in 2 of 3, both
hom died, because of disseminated peritonitis,
nd 50 hr., resp., after perforation. There
no mortalities among the 56 patients
ning, all treated by traditional gastro-
enal resection. Postoperative complications
limited to 10 cases of transient gastric
s, 6 of diarrhea, 2 of transient jaundice.
other patients had postoperative difficulties
related to surgery or the presenting disorder.
ollow-up, 1-5 yr. later, 2 of 56 had
rienced mild wt. loss, 2 reported postcibal
rome, 9 showed mild anemia and complained
arrhea. There had been no recurrences at
time of report. It is concluded that
tional gastroduodenal resection is still
therapy of choice in the treatment of gastro-
enal ulcer.

7173 EFFECT OF PARATHYROID HORMONE (PTH) ON ULCER INDUCED BY LIGATION OF THE PYLORUS. (It.) Foresti, A. (U. Messina, Italy) and A. Buda. Boll. Soc. Ital. Biol. Sper. 42(17):1088-1090, 1966.

In adult, male albino rats bearing Shay ligatures of the pylorus, pretreatment with parathyroid hormone, 0.12 Collip U/kg/day for 5 days, i.m., prior to induction of the ligature, gave approx. 60% protection against the induction of gastric ulcer. Massive ulcerations were developed by 3 of 11, as compared to 4 of 6 controls; small ulcers by 2 of 11, as compared to 2 of 6 controls. The effect was attributed to the hormone's ability to activate Ca at the level of the cellular membrane.

7174 VARIATIONS OF SERUM HISTAMINE-BINDING CAPACITY IN THE PRESENCE OF ULCERS INDUCED BY BUTAZOLIDINE. (EXPERIMENTAL STUDY.) (Fr.) Dascalakis, T. B. (Med. Clin., U. Athens, Greece), Z. Mamalis and C. Pratsica-Ougourloglou. Arch. Franc. Mal. Appar. Dig. 52(11):1033-1044, 1966.

In 5 of 5 dogs bearing gastric ulcers induced by butazolidine (75 mg/kg, i.m., single dose or in 2 equal doses, 24 hr. apart), serum histamine-binding activity was sharply reduced within 48 hr. (from 1:640-1:160) and was virtually totally suppressed (1:10) within 72 hr. The phenomenon did not reverse itself prior to death or sacrifice (max. observation time: 144 hr.). In 4 of 4 dogs in which the same treatment induced only gastroduodenal erosions, histamine-binding activity was still normal (1:640) at 48 hr., fell to 1:320 at 72 hr., then stabilized at 1:160, without subsequent reversal, at 96 hr. In 1 animal which developed hemorrhagic gastritis without ulceration, it was normal at 48 hr., 1:320 at 72 hr., normalized again by the 96th hr. No antihistamine-binding effect was exerted by the drug on 2 additional animals, which failed to develop any lesion. Among a total of 19 animals treated with butazolidine (7 of 19 not included in the above for various reasons), 16 of 19 developed gastroduodenal lesions, accompanied in 8 of 16 by liver nodules characteristic of allergic response. Such nodules could not be demonstrated in any of the 3 of 19 animals (total) which were resistant to the drug.

7175 METABOLISM AND SURGICAL MANAGEMENT OF ULCER RESECTION. (Ger.) Bartsch, W. M. (U. Bonn, Germany), A. Gütgemann, H. W. Schreiber and J. Breuer. Langenbeck. Arch. Klin. Chir. 317(2):140-159, 1967.

Acid secretion of the gastric stump, gastric proteolysis, absorption of amino acids, and blood levels of protein and amino acid were determined in normal subjects and in subjects with Billroth I and Billroth II resections. The pH in the fasting stomach was determined at rest and after stimulation in 5 cases of Billroth I and 4 cases of Billroth II. No resting acid was produced in any of these and following histamine stimulation only in 1 case with a Billroth II resection; the acid was secreted at the rate of only 2 mEq/hr. for about 45 min. Gastric proteolysis was measured in a test drink admin. to 17 normal individuals, 12 with Billroth I and 9 with Billroth II. The hydrolysis was monitored over a period of 2 hr. The normal curve was approached by that of the Billroth I patients, whereas the Billroth II curve was much depressed. The amino acid conc. of the serum was determined by an autoanalyzer; 22 amino acids were determined in 4 normal individuals and in 10 with Billroth I constructions and in 10 with Billroth II. The fasting blood levels of these amino acids showed no significant differences in the 3 groups. Analyses of sera 2 hr. after a test meal revealed an increase in the serum conc. of all amino acids in the test meal with the exceptions of asparagine, histidine, lysine, serine, arginine and glycine in the subjects with Billroth I and Billroth II. No difference was found between these 2 groups. The normal, control subjects had 100% absorption of all amino acids. Further research should make clear if these disturbances produce changes in body proteins and their metabolism. Electrophoretic separation of plasma proteins of normal subjects and those with Billroth I and II show no difference in the electropherograms. The surgical management of gastric and duodenal ulcers leads to disturbances in capacity and in the motor and secretory regulatory mechanisms, inevitably causing functional disturbances. In order to minimize these effects a number of practical steps have been outlined: extirpation of the ulcer; partial resection of the antrum leaving an oral margin on the small curvature, whenever possible only pyloroplasty; only a bordering resection of the body of the stomach in the region of the greater curvature; bilateral, selective gastric vagotomy; gastroduodenostomy according to Schoemaker and especially when suitable with the modification of Von Haberer and Winkelbauer.

7176 THE FREQUENCY OF ACUTE PERFORATED PEPTIC ULCER IN DIFFERENT POPULATION GROUPS IN ISRAEL. (Heb.) Lazarus, S. (Tel-Hashomer Govt. Hosp., Israel) and M. Modan. Harefuah 72(4):155-157, 1967.

A survey of the incidence of acute perforated peptic ulcer was carried out in 1961 and a total of 354 cases was found. All records for the years 1953-1958 were obtained from 10 hospitals, comprising 70% of the surgical beds available in Israel. The mean annual crude incidence per 100,000 population at risk was as follows: In the Jewish population, 13.9 ± 1.0 (191 cases) for European-born males, 1.5 ± 0.3 (20 cases) for European-born females; 8.8 ± 1.0 (86 cases) for Asian and African-born males, 0.2 ± 0.2 (2 cases) for Asian- and African-born females. (The difference between the male/female ratios of the two ethnic groups was significant. In b groups, the difference in incidence between mal and females was significant.) Also, 1.5 ± 0.4 (17 cases) for Israel-born males, and 0.1 ± 0. (1 case) for Israeli-born females. In Arabs a Druze, the rate was 1.4 ± 0.6 (6 cases) in male and 0.3 ± 0.3 (2 cases) in females. It was de strated that the apparent differences between the European-born, Asian-African-born, and probably also Israeli-born are due to differen in age distribution only. Rates among Yemenit as well as the Arab and Druze populations appe to be lower than in other groups, perhaps due a higher rate of deaths at home. The rates in females differ significantly from those in mal in all population groups. The small numbers involved prevented the establishing of reasons for the differences in incidence in females in the various populations. The mortality rate a the time of hospitalization was similar in bot European- and Asian-African-born males. In bo groups the mortality rate was substantially higher after the age of 60.

7177 RELATION BETWEEN MAXIMAL ACID OUTPUT OF STOMACH AND LEAN BODY MASS. (E.) Hume, R. (Southern Gen. Hosp., Glasgow, Scotla and A. G. Melrose. Brit. Med. J. 2(5543):30-3 1967.

A study is reported which tried to resolve certain aspects of previous failure to establis a significant association between max. acid output and body build by measurements of height wt., and surface area in normal patients and u patients. Results showed a significant correl between max. acid output and lean body mass in both normal adults and duodenal ulcer patients. Normals were 3 males and 5 females, aged 20-51 (mean 28.4 yr.) with no dyspeptic symptoms or family history of ulcer. Ulcer subjects were males and 3 females, aged 16-65 (mean 41.5 yr.) each with a radiologically demonstrated ulcer. Max. acid output was determined by the augment histamine test meal of Kay. Lean body mass was calculated from height and wt. by the formula of Hume on the basis of the measurement of tot body mass. A high correlation between the 2 parameters was observed. Ulcer patients showe a much wider scatter in acid output, but the correlation between the parameters was still significant. The max. acid output/kg lean body mass of the ulcer group (0.6 ± 0.2) was significantly greater than that for normals (0.3 ± 0.1).

7178 PSYCHOSOMATIC EFFECTS IN OPERATED ULCER PATIENTS. (Ger.) Zauner, J. (Lower Saxony Tiefenbrunn bei Gottingen Hosp., Germany). Z. Psychosom. Med. 13(1):24-30, 1967

After ulcer operation 87 patients suffered

chosomatic symptoms; 70 were separated into
roups on the basic of postoperation intervals
n complaints were made. The symptoms in
eral were similar in the 3 groups; the third
up showed more intense syndromes than the
er two. The complaints in general were
austion, deep depression, feelings of
dequacy, insecurity, increased excitability
n trembling, diminished sexual desire, and
otence. Vertebral column syndrome and
oulsive neurotic tendencies occurred in some
ients; in addition some became alcoholic or
ituated to analgesics; 3 showed suicidal
dencies; 3 patients exhibited agorophobia.
haracteristic complaint was the sense of
s of ability to implement plans; 1 patient
eloped priapism (contrary to the general
dition) and 1 patient showed cardiac
ptoms when under stress. In Group 1 (26
ients), the symptoms appeared immediately
er operation and continued for long periods
time without any variation. Stomach symptoms
sisted in 20 cases. Group 2 (26 patients)
bited early and late periods of symptoms,
arated by a relatively complaint-free period
-5 yr. The early symptoms of 16 cases
cerned the stomach mainly; the remaining 10
wed various neuroses. During the late period
patients developed a new set of neuroses
uding agitation, depression, impotence, etc.
up 3 cases (18) did not suffer from early
ptoms; half the number did not develop
ptoms until after the first 5 postoperative
in all cases there was an interval of at
st 1 yr. prior to onset of symptoms. Stomach
n occurred in only 5; impotence was the chief
plaint. The different neuroses were evident
this group. The generally similar character-
cs exhibited by the patients in these 3
ups may arise (a) from pre-existing bases
ggered by gastric resection, (b) from the
ree of actual physical loss of stomach tissue,
from the loss of physiological function
ernate filling and emptying, decreased
retion and possible reflex activity), or (d)
e neuropathologic relationship between gastric
er and the observed neuroses.

9 HYPERTROPHIED PLASMA CELLS IN REGIONAL
ENTERITIS. (E.) Rippey, J. H. (New
land Deaconess Hosp., Boston, Mass.) and S. C.
ners. Amer. J. Dig. Dis. 12(5):465-467, 1967.

cimens obtained from 25 patients with regional
eritis, who underwent surgical resection,
e stained with phloxine methylene blue
examined for mast cells, 1000 leukocytes
connective-tissue cells being counted in
intestinal lamina propria of each. Plasma
ls were evaluated in the above and in
controls with colonic diverticulitis. Two
cks of involved intestine from each patient
e used, and 6 μ sections were stained with
atoxylin-eosin. Plasma cells (50/slide) were
ured in deeper portions of the intestinal
na propria. The area of each cell was
ulated. Biopsy specimens from those with
rative colitis and normal controls were used
tatistical analyses. Proportions of fibroblasts,
ts, monocytes, mast cells, lymphocytes, plasma
s, eosinophils, and neutrophils were: regional
ritis, 9.1%, 8.2%, 0.002%, 25.1%, 44.8%, 3.4%,
; ulcerative colitis, 23.6%, 4.8%, 3.1%,
%, 32.3%, 5.6%, 0%; controls, 29.2%, 4.8%,
, 34.2%, 21.5%, 6.9%, 0%. The smaller
er of fibroblasts in regional enteritis was
ly significant, the difference reflecting
edematous intestinal change characteristic
his disease. The increase in plasma cells
also significant. Plasma cells were significantly
ly larger (38.8-54.4 μ^2, av. 46.8) than those
olonic diverticulitis (29.2-40.0 μ^2, av.
). The IgA proteins in regional enteritis
under study to determine whether they
esent primary or secondary participation in
inflammatory reaction.

REGIONAL ENTERITIS IN JAPAN. A REVIEW
OF 548 CASES. (E.) Yamase, K.
tendo U. Sch. Med., Tokyo), K. Masuda, S.
ada and Y. Yamada. Int. Surg. 47(5):497-502,
.

his 15-yr. study, 548 cases are reported
males, 204 females, 37 unspecified), with
disease being found in the third, second,
th and fifth decades, in order of frequency,
with children and the elderly being much less
uently affected. This age distribution
llels that of acute appendicitis. About 70%
treated within 7 days of onset, 50% within
r. Complaints, also similar to appendicitis,
uded abdominal pain in the lower right quadrant (272), nausea and vomiting (191), alternating diarrhea and constipation (96), anorexia (99), diarrhea and/or melena (32). Signs, also similar to appendicitis, included ileocecal tenderness (321), palpable ileocecal mass (58), rigid rectus muscle (205), abdominal distention (123), fever (295). Very little laboratory and roentgenogram data was available. In 367 the lesion was in the terminal ileum, within 100 cm of the ileocecal valve; in 30 in the jejunum; never upward from the duodenum. Gross findings included edema, thickening and/or narrowing (326), hemorrhage, hyperemia and swelling (229), mass formation (35), mesenteric lymph node swelling (220), bowel wall necrosis (29), hepatomegaly (11), ulcer formation (13), perforation of bowel wall (16), intestinal obstruction (2), polypoid proliferation (13). Operations included resection of ileum (103), appendectomy (249), ileocecal resection (27), right hemicolectomy including terminal ileum (9), transverse ileocolostomy (14), exploratory laparotomy (9), closure of perforated lesion (5), drainage only (2). The majority of cases were acute, but the fulminant form (resulting in diffuse or localized peritonitis) was not rare. The acute form was clinically similar to acute appendicitis, accounting for the high frequency of appendectomies (247 of 548). Considering all types of operations, recurrence was rare and clinical course uneventful. Morbidity and mortality rates were favorable compared with those reported for other countries.

7201 GRANULOMATOUS DISEASES OF THE SMALL AND LARGE BOWEL. A HISTORICAL SURVEY. (E.)(Rev.) Crohn, B. B. (1000 Park Ave., New York, N. Y.). Gastroenterology 52(5):767-772, 1967.

7203 DUODENO-JEJUNAL LOCALIZATION OF REGIONAL ENTERITIS. (It.) Monti, G. F. (U. Rome), G. Cappellini, A. Leggeri and A. Thau. Policlinico [Chir.] 74(3):137-156, 1967.

7204 NECROTIZING ULCERATIVE ENTERITIS WITH MULTIPLE PERFORATIONS AFTER EXTENSIVE INTESTINAL RESECTION FOR INVAGINATION. (Ger.) Trommer, L. (Bergen Hosp., Germany). Z. Aerztl. Fortbild. 61(9):474-479, 1967.

7205 DISACCHARIDASE ACTIVITY OF THE JEJUNAL MUCOSA AMONG SUBJECTS WITH NORMAL AND RESECTED STOMACHS. (Ger.) Drube, H. C. (U. Clin., Kiel, Germany), H. T. Hansen, U. E. Klein and K. Zielke. Deutsch. Med. Wschr. 92(21): 960-963, 1967.

Normal subjects (28, Group 1) without any evidence of gastrointestinal disease, or indication of intolerance of milk or disaccharides, were biopsied under X-ray control; the specimens were obtained 10-30 cm distal to the duodeno-jejunal flexure. Jejunal tissue was obtained from 19 subjects (Group 2) undergoing gastric resection. Group 3 comprised 20 subjects with Billroth II resections of 1-42 yr. duration from whom biopsies were taken 20-40 cm distal to the anastomoses; 14 of these Group 3 persons showed a milk intolerance manifested in cramp-like pains after intake of 250-500 ml of milk, usually followed by diarrhea. Part of all specimens of tissue were used for histologic preparations and part for the determination of the conc. of the disaccharidases: maltase (M), saccharase (S), lactase (L) and cellobiase (C). The enzyme activity was expressed in units in relation to the protein content of the intestinal mucosa. Av. values for Group 1 were: M, 266.0 U; S, 98.4 U; L, 51.2 U; C, 14.5 U. L, S, and M in this group were related in activity as 1:2:5. The av. enzyme values for Group 2 were: M, 186.1 U; S, 69.6 U; L, 40.8 U; C, 9.7 U. Group 2 had lower disaccharidase levels than the subjects from whom samples were obtained by biopsy (Groups 1 and 3). The av. values for Group 3 were nearly those for Group 1. Activities for Group 3 were: M, 265.6 U; S, 98.6 U; L, 55.7 U; C, 14.0 U. Not only were the av. activities normal in Group 3, but the values were in the normal range for all except 1 individual in whom they were depressed. There was no relationship observed between the enzyme conc. and milk intolerance in 14 individuals. Blood sugar curves in 6 of these 5 subjects were normal after oral loading with L, M, galactose and glucose. The histologic examination of the jejunal biopsies in Group 3 disclosed that 10 subjects had a normal mucosa; 7 had a low-grade inflammation of the mucosa with slight infiltration of lymphocytes, monocytes and polymorphonuclear leukocytes in the mucosa and submucosa. These 7 had normal villi; 2 others had chronic jejunitis, and 1 case had severe jejunitis with atrophied villi; this last case was the one with depressed enzyme levels.

7206 OBSERVATIONS ON THE EFFECT OF PREDNISOLONE ON THE SMALL INTESTINE AFTER MILK CONSUMPTION. (Ger.) Schmidt, G. (1st U. Med. Clin., Berlin), G. Willamowski and K. Richter. Deutsch. Gesundh. 22(14):642-644, 1967.

Fasted patients (78) received 50 ml of $BaSO_4$ suspension through a radiopaque tube in the duodenojejunal flexure. X-ray pictures of the small intestine in relief were taken after 5 min.
Milk (100 ml) was introduced through the tube
15 min. later another 50-ml vol. of contrast
material; again after 5 min. X-ray pictures we
obtained. When definitely useful films of the
tests had resulted, the patients were inj. wit
25-50 mg prednisolone; 20-25 min. later contra
material was introduced and X-ray pictures tak
for the third time. Among these 78 patients,
had histories and clinical indications of milk
incompatibility; 34 of these showed normal sma
intestine structure; 5 had a coarse, swollen r
lief. After introduction of milk the caliber
jejunal folds enlarged in 37 cases; furthermor
crossfolds appeared in the previously normal p
tern. Simultaneously the gas and liquid conte
of the intestine increased. Disturbances of
tonus arose with numerous stretch-reflex contractions. For comparison, 30 patients of the
total group with indefinite upper abdominal
symptoms and no indication of milk incompatibi
and 9 others without intestinal or allergic di
orders had no visible changes after introducti
of milk. In the 37 with enlargement of jejuna
folds in response to milk, 31 showed complete
or partial return to the normal condition 20-2
min. after prednisolone admin. Three patients
with enteritis, but no milk incompatibility,
were improved following prednisolone treatment
The intestinal manifestations recurred in 80%
of those reacting to prednisolone after cessat
of therapy.

7207 STUDIES OF ANTIBODY FORMATION AGAINS
GLIADIN AND MILK PROTEINS. II. DET
MINATION OF γM BY ULTRACENTRIFUGATION AND TREA
MENT WITH MERCAPTOETHANOL. (Ger.) Mietens, C
(U. Wurzburg, Germany). Z. Kinderheilk. 99(2)
130-139. 1967.

Sera from 33 children with celiac disease (10)
and other chronic disorders (diarrhea, dyspeps
milk allergy, malnutrition, poisoning, hepatit
etc.) showed high levels of antibodies to glia
casein and lactalbumin. These antibodies were
sedimented by ultracentrifugation at over 50,0
indicating that they belong to the macroglobul
(γM, IgM, β_{2M} or 19s) series (molecular wt.
900,000-1 million). Treatment with 2M mercapt
ethanol (specific for macroglobulins) inactiva
the majority of the antigliadin antibodies, bu
had no effect on poliovirus antibodies (which
belong to the IgG or γG series). A part of th
antibodies to lactalbumin and casein also belo
to the macroglobulin series. Sera from health
controls showed lower levels of macroglobulins
It is concluded that the induction of 19s (γM)
antibodies is a specific antigenic property of
gliadin.

7208 HOOKWORM INFECTION AND INTESTINAL
ABSORPTION AMONGST AFRICANS IN UGANDA
(E.) Banwell, J. G. (Makerere Univ. Coll.,
Kampala, Uganda), P. D. Marsden, V. Blackman,

. Leonard and M. S. R. Hutt. Amer. J. Trop.
16(3):304-308, 1967.

0 patients with hookworm, 17 had severe
ia, malnutrition and hypoproteinemia, and
had occult blood in stools. Of 30 with
torrhea and malabsorption syndrome due to
nic exocrine pancreatic disease, 21 had pan-
tic lithiasis and all had abnormal responses
ancreozymin and secretin tests. Studies
uded 72-hr. stool collection; jejunal speci-
; D-xylose excretion (5 mg dose); vitamin A
$_{12}$ absorption; small intestine studies;
urement of total hookworm load in each pa-
t by direct counting after vermifugation (5
etrachloroethylene daily for 3 days) and
ing. Hookworm (mainly Necator americanus)
ranged from 66-3073 (8 above 1000); fecal
was normal (0.4-5.6 g/day) in all 12 patients
ed; of 11 jejunal biopsies 6 showed minor
rmalities (Grade 1-3), 5 had more definite
rmalities, none had "flat" mucosa; in 8 cases
ed, D-xylose excretion ranged from 0.6-2.2
r.; fasting vitamin A levels were low in
15, but overall studies were normal; vitamin
ests performed in 4 patients were normal;
small intestine X-rays, 4 were normal and 2
d coarse intestinal folds and flocculation
in the lower portion of jejunum and ileum;
infection with other parasites was observed
. Of 30 with malabsorption syndrome, only
a significant degree of hookworm infection,
teatorrhea persisted after vermifugation.
s concluded that hookworm infection was
er the cause of steatorrhea in patients with
orm disease, nor a contributory cause of
sorption in patients with exocrine pan-
ic disease and steatorrhea.

IRON ABSORPTION IN COELIAC DISEASE OF
CHILDHOOD AND ADOLESCENCE. (E.)
M. G. T. (Trinity Coll., Dublin, Ireland),
H. Taylor and P. B. B. Gatenby. Brit. Med.
5545):151-152, 1967.

children and young adults with proven celiac
se were studied. Of 4 treated previously
gluten-free diets, none was receiving dietary
rticosteroid treatment at the time of the
. All showed abnormal jejunal mucosa. In
t excretion was in excess of 7 g/day. In
re was evidence of Fe deficiency with either
hromic anemia or low serum Fe. Controls
ere without steatorrhea or other evidence
labsorption and were matched with the celiac
for sex, age, hemoglobin and serum iron
s. No patient exhibited gastrointestinal
ing or was receiving Fe therapy at the time
e study. Absorption was measured by a
iron balance method in which 3 mg of Fe, as
t hemoglobin, was given after a standard meal
ining 2.34 mg of Fe. Hemoglobin was labeled
vo with ^{59}Fe in doses of 0.3-0.5 mc. Fecal
ction was made until less than 1% of the dose
resent in a single day's collection. Serum
and fecal fat were measured, and jejunal
biopsies were made by a Crosby capsule. Controls absorbed 36-61% (mean 46%) of the Fe dose. One celiac patient showed malabsorption (9%) while 8 absorbed 31-60% (mean 48%). No relation between Fe absorption and jejunal mucosal grade, nor between Fe absorption and fecal fat content was observed.

7210 ACQUIRED SELECTIVE VITAMIN B_{12} MALABSORPTION. (E.) Hippe, E. (Cent. Hosp. Naestved, Denmark). Scand. J. Hemat. 4(2):97-104, 1967.

A 44-yr.-old woman received local X-ray treatment after removal of a reticulum cell sarcoma from the right axilla 10 yr. previous to this study. Subsequent irradiation was admin. because of enlarged lymph node in the left axilla and abdomen. Because of megalocytic anemia and normal serum iron, she received 3 inj. of liver extract, after which hemoglobin values returned to normal. She showed impaired absorption of vitamin B_{12} and this did not improve on admin. of 50 mg pig intrinsic factor. No other symptoms of malabsorption could be demonstrated. When 50 ml normal intestinal juice was admin. in conjunction with intrinsic factor, vitamin B_{12} was absorbed normally. This indicates that the patient lacked a factor in her intestinal juice which is of importance for normal absorption of vitamin B_{12}. It is suggested that the intestinal factor ("releasing factor") is proteolytic, so that the protein complex, vitamin B_{12}-intrinsic factor, is split off to form a B_{12}-peptide which is then absorbed, and vitamin B_{12} arrives at the liver, where it is deposited, in this form.

7211 THE EFFECT OF NEOMYCIN ON THE SMALL INTESTINAL MUCOSA OF THE MONKEY. (E.) Gilat, T. (Yale U., New Haven, Conn.), J. E. Morin and H. J. Binder. Laval Med. 38(4):352-355, 1967.

The effect of neomycin on glucose absorption was studied in two 4-5 kg female Macacca Mulatta monkeys in whom Thiry-Vella loops (34-45 cm) had been constructed. After an overnight fast, a size 12 Foley catheter was inserted into each end of the loop; the loop was inflated, perfused with water and normal saline, drained, and the distal catheter clamped; 10 ml of a soln. of 9 g% glucose and 4 g% polyethylene glycol were introduced through the proximal catheter which was then clamped; after 60 min. the loop was drained and rinsed 5 times with 5 ml tap water through the distal catheter; the combined perfusate was centrifuged and the supernatant analyzed for polyethylene glycol and glucose (recoveries of 90-110% were always obtained). The amount of glucose absorbed was equal to the difference between the initial 900 mg perfusion and the amount in the perfusate. Suction biopsies were taken at 4 cm from either end of the loop. There were 2 neomycin infusion schedules: in 1 neomycin was in direct contact with loop mucosa for 24 hr. in each infusion day; in 2, 4 hr. No alteration in histology of mucosa or histochemical distribution of leucine aminopeptidase, nonspecific esterase, succinic dehydrogenase, acid phosphatase, glucose-6-phosphate dehydrogenase and LDH was observed. In both schedules, neomycin depressed glucose absorption and this effect was a function of both time and dose. The decrease returned to normal and did not occur after schedule 2. The dissociation of absorption and morphology is emphasized.

7212 MAGNESIUM DEFICIENCY COMPLICATING INTESTINAL SURGERY. (E.) Heaton, F. W. (Gen. Infirm., Leeds, England), C. G. Clark and J. C. Goligher. Brit. J. Surg. 54(1):41-45, 1967.

Of 82 patients with gastrointestinal disease, hypomagnesemia was found in 25, 9 with severe deficiency (less than 1 mg/100 ml). Thirty-seven with ulcerative colitis were examined, 29 preoperatively and 8 whose postoperative course was complicated by electrolyte disorders. Of 29, 9 were treated medically, 20 by proctocolectomy. In 16 the disease was quiescent at examination and Mg level was normal. Of 13 with active disease, 3 had subnormal levels; 1 had involvement of large intestine from rectum to hepatic flexure; 2 had total involvement. Eight with prolonged electrolyte imbalance were examined 2 or more wk. after operation, and 4 were found to have hypomagnesemia. Fifteen were admitted for diagnosis, reassessment, or operation for Crohn's disease. Of 9 with minimal clinical disturbance, only 1 had hypomagnesemia; of 6 moderate to severe, 2. Four postoperative cases had severe hypomagnesemia, complicated by severe loss of intestinal fluid, sometimes associated with sepsis and intestinal fistulae. Patients with ulcerative colitis and Crohn's disease were at greatest risk. Of 6 admitted with symptoms associated with ileostomy, 3 had hypomagnesemia (1 severe). Of 5 patients with postgastrectomy symptoms associated with diarrhea and malabsorption, 2 had hypomagnesemia. Fifteen with prolonged electrolyte imbalance for 10 or more days after abdominal surgery were studied. Two with biliary tract disease were normal, and of 8 with colonic resection for diverticulitis or carcinoma 7 were normal. Severe depletion was found in 1 patient 2 mo. after successful resection of intestinal infarction. Hypomagnesemia was also found in 1 with appendicitis complicated by sepsis and ileus; in 1 after uterine transplant for pelvic cancer; in 1 with duodenal fistula following gastric surgery for peptic ulcer. Seven with low Mg had Ca below 8 mg/100 ml. Also found were hypokalemia (5); hyponatremia (5); hypoalbuminemia (9), associated with severe hypomagnesemia in 6.

7213 WATER AND SOLUTE MOVEMENT IN THE SMALL INTESTINE OF PATIENTS WITH SPRUE. (E.) Fordtran, J. S. (U. Texas Southwest. Med. Sch., Dallas), F. C. Rector, T. W. Locklear and M. F. Ewton. J. Clin. Invest. 46(3):287-298, 1967.

Water and electrolyte movement in the jejunum wa measured during perfusion with isotonic electrol soln. in normals and patients with sprue (adult celiac, 9; tropical, 1). Water, Na, and K were absorbed in normals, but were secreted into the intestinal lumen in those with sprue (7; 1), who had diarrhea and steatorrhea. This suggests that the jejunal mucosa of these sprue patients was in a secretory state with respect to water and electrolytes. Using simultaneous diffusion rates of solutes with different molecular radii, abnormalities in the effective pore size in disease states can be detected. Since this is independent of water flow in response to osmotic pressure gradients, it can be used in disease states accompanied by abnormalities in absorptio and secretory processes involving water. In the jejunum, the ratio of urea to tritiated water diffusion was 0.2 in sprue patients, 0.8 in controls. This suggests a marked decrease in the effective pore size in those with sprue. Furthe support of this was the finding that L-xylose and erythritol, which have larger diameter than urea, were nonabsorbable in the sprue intestine. Studies with antidiuretic hormone showed that th permeability barrier of the small intestine was not controlled by the posterior pituitary gland. The secretion of water and electrolytes and the reduced effective pore radius in patients with sprue are not necessarily interdependent. Two with moderate celiac sprue (biopsy) who did not have diarrhea or steatorrhea did not secrete water or electrolytes, but did show a marked decrease in effective pore radius.

7214 MODIFICATIONS OF INTESTINAL ABSORPTIO OF p-AMINOHIPPURIC ACID IN ANCYLOSTOMIASIS. (It.) Loschiavo, F. (U. Messina, Italy) and D. Gallo. Arch. Ital. Sci. Med. Trop 47(9-10):233-248, 1966.

Among 10 normal subjects, mean serum levels of p-aminohippuric acid were calculated at interva of 10, 20, 30, 60 and 90 min. after ingestion o 6 g of the substance in the form of its Na salt as follows: 1.16, 3.20, 2.82, 2.42 and 1.93 mg/liter, resp. Comparable tabulations among 1 subjects with confirmed ancylostomiasis were 0. 2.20, 2.00, 1.49 and 1.03 mg/liter, resp. It i concluded that the infestation involves a statistically significant diminution of intestinal mucosal absorption of p-aminohippuric acid, pro ably due to a combination of the effects of intestinal mucosal lesions and a disturbance of intestinal biochemistry which is mediated direc by the presence of the parasite.

7215 INTESTINAL ABSORPTION IN PATIENTS UNDERGOING ESOPHAGEAL-ILEAL-COLONIC RECONSTRUCTION FOR BENIGN ESOPHAGEAL STENOSIS. (It.) Balzola, F. (U. Turin, Italy), A. Pera, R. Dematteis and G. Bricco. Minerva Gastroent. 12(4):123-127, 1966.

Surgical reconstruction of the esophagus, ileum

d colon was performed on 2 boys, aged 14 and
, a 17-yr.-old girl and 4 men, 3 women, aged
-60. All were suffering from benign esophageal
enosis; all recovered without incident and were
le to resume their normal occupations. Total
cal vol. per 24 hr. was increased after surgery
6 of 10, with an increased frequency of
fecation in 5 of 6; 6 of 10 showed increased
imination of fecal nitrogen; 1 of 10 developed
eatorrhea; 4 of 10 developed mild hypocarotinemia
d 1 of 10 developed severe hypocarotinemia as
rt of a generalized malabsorption syndrome.
is patient, a 26-yr.-old woman, had also under-
ne ablation of the esophagus and total abdominal
gotomy. In 8 of 10, urinary excretion of xylose
s reduced considerably, but remained within
rmal limits in 6 of 8. In 1 patient, who had
eviously undergone gastroenteroanastomosis,
e second intervention failed to increase or de-
ease an existing impairment of digestive func-
on, which, however, did not include signs of
absorption syndrome.

6 LEUCOCYTE ASCORBIC ACID LEVELS IN
PATIENTS WITH MALABSORPTION OR PREVIOUS
STRIC SURGERY. (E.) Williamson, J. M.
uthern Gen. Hosp., Glasgow, Scotland), A.
dberg and F. M. L. Moore. *Brit. Med. J.*
543):23-25, 1967.

ascorbic acid levels were measured in 26
ients who either had intestinal malabsorption
; 6 men and 7 women; av. age 50 yr.; 2 with
opathic and 5 with unclassified steatorrhea,
ach with multiple diverticulae, reticulum-cell
coma and pancreatic steatorrhea, and 3 mis-
laneous who were thought to have adult celiac
ease) or had undergone gastric surgery (13;
en and 7 women; av. age 59 yr.; 6 had gastro-
erostomy and vagotomy, 4 Polya partial gas-
ctomy and 1 each Billroth I gastrectomy,
al gastrectomy and pyloroplasty alone) and
pared with those in 26 control subjects. The
n WBC ascorbic acid level in both of the
mer groups together was 11.7 $\mu g/10^8$ WBC, com-
ed to 20.8 $\mu g/10^8$ WBC in controls; this was
tistically significant. In the malabsorption
up alone, it was 10.7 $\mu g/10^8$ WBC and in the
tric surgery group it was 12.7 $\mu g/10^8$ WBC;
in, the difference observed between the mean
each group and that of the control group was
tistically significant. Mean WBC ascorbic
d level in all patients with steatorrhea,
ardless of the group, was 10.0 $\mu g/10^8$ WBC,
ch was not significantly different from the 2
ups as a whole. In 24 of the 26 patients
died, the diet history was considered reliable,
in these cases the mean daily intake of
amin C was 41.1 mg/day (with a range of 12-91
day); none of the patients had a dietary in-
e of vitamin C below 10 mg/day, the minimal
tective level against scurvy. In 12 of 26
trols, the mean intake of vitamin C was 60.0
day. Five of 26 patients had clinical evidence
increased capillary fragility and 3 had purpura
the arms and/or legs. The platelet count was
within the normal range in all patients. It is suggested that patients with intestinal malabsorption and those who have undergone gastric surgery, especially the elderly, should have their diet supplemented with vitamin C.

7217 LOW SERUM CHOLESTEROL LEVELS AND SUBCLINICAL MALABSORPTION. (E.) Robins, S. J. (U. Puerto Rico Sch. Med., San Juan), M. Garcia-Palmieri and C. Rubio. *Ann. Intern. Med.* 66(3):556-567, 1967.

Men (102 of 136, 45-62 yr. old) who had been examined at a Heart Program within a prescribed period of time and whose serum cholesterol level was 160 mg/100 ml or less (61 of 77 men) and 260 mg/100 ml or more (41 of 59) were given D-xylose absorption tests. All were currently living in metropolitan San Juan or a rural community in the central mountains of Puerto Rico (Naranjito). Of those with low cholesterol levels, 56%, as compared to only 15% of those with high values, had xylose excretions equal to or less than 4.0 g and 20% of those with low cholesterol levels had what was considered to be an unequivocally normal test response (greater than 5.0 g/5 hr.). In the absence of any observed significant dietary differences, malabsorption appeared to be the mechanism responsible for the low serum cholesterol values. As a group, those with impaired xylose absorption were clinically indistinguishable from nonaffected individuals; relevant gastrointestinal symptoms occurred with comparable frequency. Although predominantly of rural residence, the malabsorbing group was of favorable socioeconomic circumstances. Extended investigations in those with xylose excretions of less than 4.0 g provided corroborating evidence of small-intestinal disease in conjunction with usually absent to minimal jejunal histologic abnormalities. It is suggested that in Puerto Rico, where mortality from coronary heart disease in men in the 45-64 yr. old age group is half of that in the United States, widespread, occult malabsorption, through its postulated effect on cholesterol, may play a major and decisive protective role.

7218 STUDIES ON THE ABSORPTIVE DEFECT FOR TRIGLYCERIDE IN ABETALIPOPROTEINEMIA. (E.) Ways, P. O. (U. Washington Sch. Med., Seattle), C. M. Parmentier, H. J. Kayden, J. W. Jones, D. R. Saunders and C. E. Rubin. *J. Clin. Invest.* 46(1):35-46, 1967.

In 3 patients with confirmed abetalipoproteinemia, p.o. biopsies of the duodenum were obtained following *ad libitum* (fasting) diet and various lipid regimens including fat-free, added fat and single load diets and then compared with normal preparations. Fasting patients showed larger and more numerous lipophilia vacuoles than in normal fasting subjects and also an increased (1.5-3.5 times) total lipid content which was mostly triglyceride. The triglyceride fraction (as percentage of total lipid) was increased from 2-3.5 times and as percentage biopsy wet wt. was increased from 2.5-11 times. These findings were confirmed by thin-layer chromatography. In one patient who was maintained on a fat-free diet (0.3 g fat/day) for 34 days, serial studies showed a progressive decrease in mucosal lipophilia within the absorptive cells of the upper third of the villus. At 34 days, excess lipophilic particles were observed in the villus tip and both total lipid and triglyceride were still increased. Periods of fat diet supplementation after fat-free programs resulted in increased fat content of mucosal specimens, improved coefficient of fat absorption during a 14-day trial of 8.5 g of fat/day plus 28 g corn oil/day and a correlation between stool lipid excretion/day and both mucosal lipid and triglyceride as percentages of wet biopsy wt. and total lipid fraction, resp. After acute fat load, the definite qualitative changes in both mucosal and plasma lipids were not as great as in normal individuals. The route by which dietary fat is absorbed in patients with abetalipoproteinemia who were given extended programs of various types of dietary fat is not known at present.

7219 GASTRECTOMY AND IRON ABSORPTION: EFFECTS OF BLEEDING, IRON LOADING AND ASCORBIC ACID IN RATS. (E.) Rieber, E. E. (727 Bronx River Rd., Bronxville, N. Y.), M. E. Conrad and W. H. Crosby. Proc. Soc. Exp. Biol. Med. 124(2):577-580, 1967.

Male albino WRCF rats were fed a standard rat and mouse diet containing 15 mg of Fe/100 g of dry wt.; the rats consumed approx. 2 mg Fe/day on this diet. Half of the rats were gastrectomized 1 mo. before initiation of Fe-absorption studies. Normal controls were 48 rats of comparable wt. Rats were Fe-loaded by i.m. inj. of 25 mg of Fe as dextran-Fe, 7-14 days before Fe-absorption studies. The latter were performed by admin. of test doses of radioiron; test soln. contained 0.25 μc of ^{59}ferric chloride ($^{59}FeCl_3$) and 0.25 mg of elemental Fe as ferrous sulfate ($FeSO_4$), brought to a vol. of 1 ml with Fe-free distilled H_2O. Gastrectomized rats developed an anemia that responded to parenteral doses of Fe. Negative benzidine tests on fecal collections from 30 of 32 animals indicated that anemia was not caused primarily by intestinal bleeding. Normals absorbed significantly more radioiron from test doses of $FeSO_4$ than gastrectomized rats (13 ± 3.8 vs. 6.9 ± 2.4%). Addition of ascorbic acid (10 mg) to test doses increased the amount of ^{59}Fe absorbed by both groups, but the differences were insignificant (17.5 ± 8.2% vs. 12.7 ± 5.9%). Fe-loaded gastrectomized animals absorbed approx. the same amount of ^{59}Fe from test doses as normals that received i.m. inj. of dextran-Fe (5.6 ± 3.7% vs. 4.2 ± 1.0%). If Fe-loaded rats were given test doses of radioiron containing ascorbic acid, both intact and gastrectomized rats absorbed similar amounts of Fe (7.9 ± 2.6% vs. 6.9 ± 2.2%). Similar studies in rats that were bled and fed a milk diet revealed marked differences in Fe-absorption between all groups of control and gastrectomize rats. Intact animals absorbed 59.1 ± 12.1% vs. 17.7 ± 3.8% in gastrectomized rats. Similar differences occurred if ascorbic acid was added to the test dose (55.1 ± 13.6% vs. 19.8 ± 2%), if Fe-loaded-phlebotomized rats were given p.o. dos of Fe containing ascorbic acid (30.4 ± 14.1% vs. 9.2 ± 5.1%) or if the rats had been overloaded before bleeding (57.5 ± 12.7% vs. 12.4 ± 4.3%). Even Fe-loaded rats that were bled only 2.5 ml absorbed significantly greater amounts of ^{59}Fe from test doses than similarly treated gastrectomized rats (24.4 ± 6.0% vs. 7.1 ± 2.4%). It is suggested that Fe-deficiency occurred after gastrectomy because of an inability to adjust absorption in response to changes in the body requirement.

228 COMPARISON OF RECTOSIGMOID MOTILITY IN
NORMAL CHILDREN, CHILDREN WITH RECURRENT
BDOMINAL PAIN, AND CHILDREN WITH ULCERATIVE
OLITIS. (E.) Kopel, F. B., I. C. Kim and G. J.
arbero (Children's Hosp., Philadelphia, Pa.).
ediatrics 39(4):539-545, 1967.

ectosigmoid motility was studied in 18 children
ith recurrent abdominal pain without evident
rganic etiology, in 10 children with ulcerative
olitis, and in 18 normal children. Motility was
tudied using saline-filled open-tipped polyethy-
ene tubes (internal diameter 2 mm), inserted to
mm and 12 mm from the anus for simultaneous
ecording, connected to strain gauges (Statham
23B) with readout on a multichannel recorder.
ube patency was maintained by constant infusion
f saline at 9 ml/hr. When necessary, colonic
ube position was checked by fluoroscopy. After
ube insertion, a baseline of rectosigmoid activity
as established over 30 min. Then 0.5 mg prostig-
ne methyl sulfate was inj. s.c. and the following
min. of rectosigmoid activity was recorded.
hose with recurrent abdominal pain showed a
eightened response to prostigmine with increased
ectosigmoid motility. These results are
milar to those in adults with the spastic colon
riety of irritable colon. On the basis of
inical and physiological similarities, it is
ggested that the adult and childhood disease
ntities are the same. Children with ulcerative
olitis showed reduced rectosigmoid activity.

229 MEGASIGMOID SYNDROME IN DIABETES AND
NEUROLOGIC DISEASE. REVIEW OF 13 CASES.
.) Berenyi, M. R. (Bird S. Coler Hosp., Welfare
sland, N. Y.) and G. S. Schwarz. Amer. J.
stroent. 47(4):311-320, 1967.

tients (4 men, 9 women) were 39-89 yr. old.
existing diseases were: diabetes mellitus (2
n, 5 women); diabetes mellitus and Parkinson's
sease (0,2); Parkinson's disease (2,0); traumatic
raplegia (0,2). Signs and symptoms included
stended abdomen (4,9); volvulus and subsequent
rgery (2,2); constipation (0,4); prolonged
arrhea (4,5). Bowel habits of constipation,
arrhea, and normal, resp., were found in:
abetes (1,6,0); diabetes and Parkinson's
,1,0); Parkinson's (0,2,0); traumatic paraplegia
,0,0). Surgery for reduction of sigmoid volvulus
s necessary in 4 (2 men, 2 women). Volvulus
s reduced in 2 women by insertion of a high
ctal tube. Ba enema was capable of deflating
volvulized sigmoid even in those eventually
quiring surgery. Ba enema established the
agnosis easily by filling the distended sigmoid
op with contrast material. When distended,
e sigmoid tended to extend into the right half
the abdomen as well. The incidence of diabetes
llitus (9 of 13) was 3 times higher than that
the rest of the hospital population (22%).
arrhea occurred in most patients, especially
abetics. It is suggested that visceral diabetic
neuropathy may have contributed to or increased development of megasigmoid in 9. Dysfunction of the autonomic nervous system was implicated in all 13. No anatomical changes were observed in submucosa or myenteric nerve of excised colon.

7230 AN ELECTRON-MICROSCOPE AND HISTOCHEMICAL STUDY OF MELANOSIS COLI. (E.) Ghadially, F. N. (U. Sheffield, England) and E. W. Parry. J. Path. Bact. 92(2):313-317, 1966.

Colon tissue was obtained from sigmoidoscopic examination of patients with melanotic colons. Specimens were fixed in osmium tetroxide, embedded in araldite, 0.5-1.0 μ sections were stained with metachromatic blue (60°C) at pH 6.8 for light microscopy and sections for electron microscopy were unstained or stained with lead citrate. For light microscopy and histochemistry, melanotic colons were fixed in formalin, samples inbedded in paraffin, stained with hematoxylin and eosin and the following methods: Fontana, Prussian blue, periodic acid-Schiff, Ziehl-Neelsen, nile blue sulfate, bleaching with potassium permanganate and oxalic acid, and Unna-Pappenheim. Frozen sections were stained with oil red O and some were examined under UV for fluorescence. Small squares of colonic mucosa were prepared for demonstrating melanocytes. Light microscopy and histochemistry showed melanocytes to be located in the mucosa and submucosa just below the muscularis mucosae and confirmed that the pigment gives many reactions for both lipofucsin and melanin. Electron microscopy showed that the large melanocytes had oval nuclei with indentation(s), numerous smooth-walled vesicles, some mitochondria, scanty endoplasmic reticulum, and many ribonucleoprotein particles free in the cytoplasm; pigment granules of complex morphology; plasma cells lacked pigment particles; the submucosa was thickened and edematous; small and large collections of electron-dense particles in the smooth muscle fibers of the muscularis mucosae; pathological lesions of epithelial cells, some with large deposits of glycogen, and widening of intercellular junctions. Granules in epithelial cells arise from areas of focal cytoplasmic degeneration involving mitochondria, endoplasmic reticulum, and glycogen.

7231 PATHOLOGY AND PROGNOSIS OF CANCER OF THE COLON AND RECTUM. (E.) Morson, B. C. (St. Mark Hosp., London) and H. J. R. Bussey. Schweiz. Med. Wschr. 97(18):568-570, 1967.

Data (from 1928-1962) for 3596 patients with rectal cancer is presented. Crude 5-yr. survival rate was 34.7%, corrected survival rate ("cure" rate = crude survival rate expressed as a % of expected number of 5-yr. survivors in a similar population sample, allowing for death from other causes) was 41.8%, corrected rate for inoperative (radiated) cases was 3.4%, and that for operated (radical and palliative) was 57.4%. At 10, 15 and 20 yr., the corrected rates were 51.5%, 49.7% and 50.7%, resp. According to Dukes A, B, C system, corrected 5-yr. rates were 97.7%, 77.6% and 32.0%, resp. (all cases 57.4%); 10-yr. were 97.3%, 70.0% and 26.2%; 15-yr. were 90.4%, 68.8% and 25.2%; 20-yr. were 95.2%, 72.3% and 25.8%. Only 3.3% of 2305 cases from 1948-1962 were early rectal cancer. Rectal cancer was rarely detected at an early stage, and individual pathologists could not expect to see more than occasional examples of so-called 'malignant polyps'. Because of low frequency of early diagnosis, the incidence of Dukes A, B and C cases for each 5-yr. period (1928-1962) was calculated. Dukes A was constant at 15%; B, constant at 35%; C, constant at 50%. This shows that rectal cancer is not being diagnosed any earlier now than in 1928, but this must be considered in light of the 1953-1957 resectability rate of 93.1% as compared with 46.6% in 1928-1932. About 56.6% of intestinal cancers had a preceding 'pre-invasive' or benign phase. When extent of spread was limited to bowel wall, incidence of origin in benign tumor was 18.3%; when spread in continuity involved extramural tissues, incidence was only 7.6%; overall incidence of origin in benign tumor for all 2305 cases examined was 10.6%. Of 3381 patients undergoing surgery for removal of rectal or colonic malignant tumor, 1.6% developed a second primary tumor in residual bowel (corrected rate expected to be 3.5%), the time interval varying from 3 mo.-29 yr. (av. 8.5 yr.). A patient with adenomatous polyps in the first operative specimen had twice the chance of developing a second primary intestinal cancer than when no such polyps were present (2.67% as opposed to 1.14%).

7232 RECURRENCE AND MORTALITY RATES IN SIGMOID VOLVULUS. (E.) Hines, J. R. (Northwestern U. Med. Sch., Chicago, Ill.), R. E. Geurkink and R. T. Bass. Surg. Gynec. Obstet. 124(3):567-570, 1967.

A study of 45 patients (28 male, 17 female), av. age 66 (31-92), with sigmoid volvulus was reported. All 45 had obstipation and distention. Reduction by proctoscopy and well-lubricated, long rectal tube was successful in 29 of 37 cases. Reduction by laparotomy was done in 11 cases. Of 14 patients given Ba enemas before reduction, 6 exhibited reduction of the volvulus due to the Ba column and 6 showed spontaneous reduction. Only 2 patients died with an unreduced volvulus. Of 52 early reductions, there were 9 early recurrences and 43 original reductions. Recurrences followed every method of reduction, for an overall rate of 90%. Overall mortality rate was 40%. Only 1 of 13 patients receiving conservative therapy was alive after 18 mo. Of 19 patients who had simple elective sigmoid resection with end-to-end anastomosis, 18 survived. Treatment involving elective sigmoid reconstruction by primary end-to-end anastomosis is recommended immediately after reduction.

7233 SELECTIVE ARTERIOGRAPHY IN CANCER OF THE RECTUM. (Fr.) Parturier-Albot, (Coll. Med. Hosp., Paris), C. Hernandez, M. Champeau, L. Boccon-Gibod and G. Albot. Sem. Hop. Paris 43(18/4):1177-1190, 1967.

Arteriography (inferior mesenteric artery) was performed in 9 patients with carcinoma of the rectum; angiographic examinations (venous in 2 cases, arterial in 4 cases) were also performe on 6 operative specimens. Dilatation of the nutrient artery, abnormal distribution of the arteries and capillaries, and early venous ret were noted in the malignant tumors. In additi to these characteristic findings, large tumors showed amputation of certain venous trunks and an absence of early venous return in the prese of deep infiltration of the disease. Cure of the tumors (in 4 cases) following contact radi therapy was accompanied by disappearance of al the angiographic signs of malignant disease. these patients, disappearance of the disease was confirmed by histological examination of surgical specimens.

7234 THE CECAL APPENDIX AND RHEUMATIC FEV (HISTOLOGIC STUDIES.) (It.) Cervin (U. Rome), M. Palleschi and G. Stella Therapeutikon 7(4-5):267-285, 1966.

A histopathologic study was made of 100 vermif appendices derived from 47 male and 53 female patients, aged 3-42 yr. (mean age, 19). A his of rheumatic fever was elicited from 4 of 100, a history suggesting disorder of the heart val from 14 of 100 (verified in 4 of 14). There w no statistically significant differences betwe rheumatic and nonrheumatic patients as concern tonsillectomy or the course of severity of appendicitis. No histologic or other differen could be demonstrated in the appendices derive from rheumatic patients.

7235 BASALOID CARCINOMA OF THE ANAL CANAL (E.) Pang, L. S. C. (St. Mark's Hos London) and B. C. Morson. J. Clin. Path. 20(2 128-135, 1967.

Of 206 cases (17 men, 19 women, 41-80 yr., av. 60) of squamous cell carcinoma of the anus and anal canal, 36 (18%) were basaloid. Exact tum localization was possible in 33. In 23 the tu was entirely above, in 6 mainly above, in 4 astride the anal valves (dentate line). Tumor were divided into 3 groups on the basis of the amount of palisading and the extent to which t retained their capacity to form circumscribed clumps of cells: well-differentiated basaloid carcinoma (10); moderately differentiated (12) poorly differentiated and anaplastic (14). Because of advanced disease, 6 received no sur treatment, but only radiotherapy, none survivi 5 yr. Of 3 undergoing local excision of prima tumor, 1 died within 3 yr., and 2 are alive at 1 and 8 yr., resp. Excision of rectum and ana region was performed in 27. There were 3

toperative deaths, loss of 1 to follow-up,
3 are alive at less than 5 yr. Of the re-
ning 20, 11 (55%) have lived more than 5 yr.,
25%) more than 10 yr. Of the 9 who died before
r., 8 died of recurrence. Of those undergoing
tal excision, 6 had hemorrhoidal lymph node
olvement, 2 had hemorrhoidal and inguinal, 2
inguinal only. Five-yr. survival was 40%; the
urvivors were alive after 10 yr. Of 10 with-
lymph node metastasis the 5-yr. survival was
. None had shown signs of recurrence; 2 were
ing after 10 yr. It is concluded that cases of
l-differentiated and moderately differentiated
aloid carcinomas have a good prognosis, even
n lymph node metastasis has already taken place.
prognosis for anaplastic basaloids is poor
n in the absence of lymph node involvement.

5 TECHNIC OF ABDOMINOPERINEAL RESECTION
OF THE RECTUM. (E.) Localio, S. A.
v York U. Med. Ctr., N. Y.), W. R. N. Grier
A. H. Postel. Surg. Gynec. Obstet. 124(3):
-602, 1967.

echnic of abdominoperineal resection of the
tum, conforming closely to that originally
cribed by Miles in 1910, is described; refine-
ts of the original technic include the placement
construction of the stoma, obliteration of
pelvic dead space and the primary closure of
perineum. The colon stoma is brought through
upper end of the main laparotomy incision and
efully sutured to the edges of the peritoneum
fascia. The open end is sutured to the skin,
the pelvic peritoneum is not closed. A suture
e that is prone to disrupt and cause internal
iation and intestinal obstruction is thus
inated. Descent of the omentum and small
estine to obliterate the pelvic dead space
ws primary suture and healing of the perineum.
2 abdominoperineal resections performed with
procedure, there was no intestinal obstruction
to pelvic adhesions. One patient required
rotomy and division of an obstruction adhesion
the small intestine to the stump of the ligated
rior mesenteric vessels; 3 other patients with
l intestinal ileus were successfully managed
ntestinal suction.

INFLAMMATORY LESIONS OF THE LARGE INTES-
TINE IN VENEZUELA. (Sp.) Celli, B. B.
. Med., Central U. Venezuela, Caracas).
N. 20(4):727-753, 1966.

review of 2,500 autopsy records, 104 cases
found in which ulcerative colitis was either
immediate cause of death or a major contribut-
factor. Included were 51 cases of bacterial
rocolitis; 29 of amebic dysentery; 7 of idio-
ic ulcerative colitis; 6 of stenosing, rectal
hogranuloma of venereal origin; 2 cases, each,
iverticulitis, colitis due to schistosomiasis,
ngyloidiasis and intestinal tuberculosis; 1
each of cystic colitis with pellagra,
ntidiasis and typhoid fever. Although diverticulosis was evident in 150 of the total autopsy group, diverticulitis was found in only 2, as noted above. Both were women, aged 80 and 85, resp., and both were suffering from chronic peritonitis. Although the age range in other patient groups was very wide, the patients with idiopathic ulcerative colitis (4 men; 3 women) ranged only from 23-40 yr. The disorder was the immediate cause of death in 4 of 7; in 2 of 7, the immediate cause was pneumonia; in 1 of 7, it was acute alcoholism. Among patients with amebic dysentery, 17 of 29 had perforated ulcers of the colon; 17 of 29 had hepatic lesions and 6 of these had perforated into the peritoneal cavity. Among patients with bacterial enterocolitis, the disorder, which was the immediate cause of death in 30 of 51, was limited to the colon in 39 cases, involved both the small and large intestine in 11, and involved the entire gastrointestinal tract, including the stomach and esophagus, in 1 patient. No cases of Crohn's disease were found in the autopsy records which were reviewed for this study.

7238 CONSERVATION OF THE INFERIOR MESENTERIC ARTERY BY SKELETIZATION IN ANTERIOR RESECTIONS FOR RECTOSIGMOID CANCER. (It.) Virno, F. (U. Rome,), A. Aureggi and F. Barillari. Policlinico [Chir.] 73(3):127-152, 1966.

A total of 19 patients with rectosigmoid cancers (12 men, 7 women; aged 60-70 yr.) were treated by anterior resection of the rectum accompanied by section of the inferior mesenteric artery at its source. The tumor was found in the sigmoid colon in 10 of 19; in the rectal ampulla in 9 of 19. Intestinal continuity was restored by side-to-side anastomosis in 6 of 19, by end-to-end anastomosis in 13 of 19. The surgical mortality rate was 15.7% (3 of 19) and subsequent partial or total dehiscence of the anastomosis occurred in 3 of 16 and 1 of 16 remaining, resp., between postoperative day 7-11. Anterior resection of the rectum with conservation of the inferior mesenteric artery was practiced in 41 patients with similar tumors (22 men, 19 women; aged 28-87 yr., median age was 59 yr.). The tumor was found in the sigmoid colon in 24 of 41; in the rectal ampulla in 4 of 41; at the rectosigmoid junction in 11 of 41. Simultaneous cancerization of the ascending and sigmoid colon was seen in 2 of 41. Intestinal continuity was restored by side-to-side anastomosis in 11 of 41; by end-to-end anastomosis in 30 of 41. The surgical mortality rate was 12% (5 of 41), with no subsequent partial or total dehiscence of the anastomosis among the 36 patients remaining. In addition to the indicated advantages of the second technic, a study of the material excised from both groups of patients showed that the medial hemorrhoidal artery was absent bilaterally in 20%, so that an adequate blood supply to the rectal ampulla could not be guaranteed if the inferior mesenteric artery was ligated or sectioned.

7239 MECONIUM BLOCKAGE SYNDROME. (E.) Mikity, V. G. (U. Southern California

Sch. Med., Los Angeles), J. E. Hodgman and J. Paciulli. Radiology 88(4):740-744, 1967.

The incidence of meconium blockage was 1/1,000 admissions (41 cases reviewed) with a sex ratio of 2:3 in favor of male patients. Initial symptoms included a characteristic green-stained vomitus and abdominal distention observed between 9-80 hr. after birth. Lethargy, irritability, and respiratory distress developed in some infants. Initial radiographic appearance was that of low intestinal obstruction. Use of Ba enema proved helpful in differentiation between meconium blockage and other conditions including meconium ileus, ileal atresia and congenital megacolon as well as in relieving bowel distention. Five infants were successfully treated by digital examination only, while all except 3 of the remaining infants showed alleviation of distention following Ba enema. Some cases required saline or peroxide enemas. Symptoms lasted for 3-12 days in all patients. Three infants with meconium blockage underwent colostomies during the newborn period due to increasing abdominal distention and debilitation. Three premature infants died of unrelated causes (1 of meningitis and 2 of intraventricular hemorrhage). All of the remaining infants, except one who developed congenital megacolon, showed subsequent normal intestinal function. Markedly reduced values of trypsin (0-35 μg/g) were noted within the first 3 days of life in stool specimens from 3 infants, but the values normalized by 5 days of age.

UROLITHIASIS IN CROHN'S DISEASE AND
ULCERATIVE COLITIS. (E.) Gibson,
. (Pembury Hosp., Tunbridge, Wells, Kent,
and). Guy. Hosp. Rep. 115(4):443-447, 1966.

patients with ulcerative colitis and one
Crohn's disease in association with
ithiasis were treated. One patient had a
acid stone removed 6 yr. after undergoing
colectomy and ileostomy for fulminating
rative colitis. Serum uric acid was normal.
cond patient was treated by nephrectomy for
rge staghorn calculus 17 yr. after ileostomy
partial colectomy for ulcerative colitis.
stone was composed of uric acid with small
es of calcium. The urine was not infected
was uniformly acid. Six yr. after original
ery, the patient suffered an episode of right
l colic which subsided after passage of
el in the urine. A third patient who had
treated for 12 yr. for ulcerative colitis,
loped a right renal colic which subsided in
ys after passage of gravel in the urine.
tion of the renal pelvis and upper ureter
shown by i.v. pyelogram. A fourth patient
a 1 yr. history of ulcerative colitis
aled a staghorn calculus at barium enema,
subsequently succumbed to a perforated
enal ulcer 3 days after nephrectomy. A
h patient who had been treated by numerous
ical procedures for Crohn's disease (15 ft.
mall intestine resected) had passed numerous
l stones during the last 3 yr. Multiple
ities were observed in the renal papillae by
y. One stone examined consisted of calcium
ate. This patient revealed only a slight
bolic acidosis. Factors suggested for stone
ation in these patients probably involve a
eased vol. of concentrated urine and lowered
ary conc. of sodium and potassium ions.

NONSPECIFIC GRANULOMATOUS, SEGMENTAL
COLITIS. (It.) Cosmacini, G.
giore Hosp., Milan, Italy) and G. Bettinelli.
. Fisiopat. Clin. Ter. 38(2):86-126, 1966.

tailed discussion follows a summary
entation of clinical symptoms, localization
esions, radiologic findings, surgical find-
and histologic findings made for a total of
dult patients (11 men, 10 women; aged 21-59
and 1 infant (a 5 yr.-old boy) who were
ated for nonspecific, regional, granulo-
us colitis. Presenting symptoms consisted
bdominal pain (22 of 22), tumefaction
of 22), disturbances of the lower tract
of 22) and fever (8 of 22). In 7 of 22,
lization was essentially within the colon
lf (3 of 7 = sigmoid; 2 of 7, each, = in the
t and left colon); in 15 of 22, the cecum
ed as an epicenter for the spread of the
rder. It is concluded that distinguishing
e 2 basic forms of the disorder makes it
ible to explain the widely variant histologic findings encountered as nothing more than different chronologic phases of the same disease entity; which, in turn, may be defined in terms of a generic response on the part of the organic substrate, rather than in terms of specific characteristics of the granulomatous process, as such. Sub-groups under the general category of cecal epicentricity included filling defects; funnel-like, stenosing constriction; total obliteration of the cecal lumen by hyperplastic granulomatous tissue; girdle-like, stenosing constriction; paracecal tumefaction. A type of belt-like, stenosing constriction of primarily colonic origin was also observed.

7291 ON THE TREATMENT OF IDIOPATHIC PROCTOCOLITIS WITH IMMUNOSUPPRESSIVE DRUGS. (It.) Caprilli, R. (U. Rome), G. Badalamenti and R. De Santis. Policlinico [Med.] 73(6):349-360, 1966.

Azathioprine (Imuran = 2.5 mg/kg/day x 20-180) was admin. to 7 patients with ulcerative colorectitis (6 men, 1 woman; aged 23-58; 5 of 7 without previous therapy; 2 of 7 previously resistant to sulfonamides and corticosteroids). Clinical responses were evaluated in terms of normalization of feces and voiding rhythm, reduction or disappearance of abdominal pain and fever, improvement of general status and radiologic and procto-sigmoidoscopic confirmation of regression of lesions. Overall clinical responses were tabulated as good in 5 of 7 cases, fair in 1 of 7, no response in 1 of 7. Side effects were limited to 2 cases of anorexia + mild, spontaneously reversing leukopenia (accompanied in 1 of 2 by mild erythrocytopenia, bromsulfalein retention and increase of indirect serum bilirubin). In 6 of 7 cases, treatment induced a marked reduction of lymphoplasmocytic infiltration of the intestinal mucosa, but reduction of circulating, monospecific immunoglobulin -G, -A and -M antibodies occurred in only 1 of 3 in whom these were demonstrable prior to initiating treatment.

7292 A NOTE ON SERUM COMPLEMENT ACTIVITY WITH PARTICULAR REFERENCE TO ULCERATIVE COLITIS. (E.) Fogel, B. J. (U. Miami Sch. Med., Fla.), W. A. Hook and E. Polish. Milit. Med. 132(4):282-285, 1967.

Mean serum complement activity was found to be low in 10 patients with acute glomerulonephritis (68.3 $C'H_{50}$/ml) and in 5 patients with lupus nephritis (53.4 $C'H_{50}$/ml), but normalized during convalescence in the former group. A normal range of 154-250 $C'H_{50}$/ml was obtained from 15 control subjects. High mean titers were noted in 5 children with acute rheumatic fever with carditis (333 $C'H_{50}$/ml) and in 10 children with residular valvular disease (222 $C'H_{50}$/ml). Normal or somewhat elevated levels were found in

3 older patients with rheumatoid arthritis, in 2 children with dermatomyositis and in 1 boy with anaphylactic purpura. In 16 patients (14 mo.-51 yr. of age) with active ulcerative colitis, mean serum level was 270 $C'H_{50}$/ml. and only two of these patients had values less than the control level. A 14 mo. child with a 1 yr. history of colitis who presented an initial serum complement level of 353 $C'H_{50}$/ml showed a significant reduction to 107 $C'H_{50}$/ml 1 yr. later during a course of septicemia due to Friedlander's bacillus. Studies in patients with acute nephritis and lupus nephritis evidenced some support that the lowered serum complement levels observed were the result of a fixation of complement to tissue antigen-antibody complexes. The normal or elevated complement levels seen in patients with active ulcerative colitis, however, may reflect the fact that an immunologic mechanism may be operative in the pathogenesis of the disease.

7293 AUTOANTIBODIES IN ULCERATIVE COLITIS. (E.) McGiven, A. R. (Monash U., Melbourne, Australia), T. Ghose and R. C. Nairn. Brit. Med. J. 2(5543):19-23, 1967.

Sera from 54 patients (23 males, 31 females; 10-82 yr. old) with ulcerative colitis and from 194 controls (consisting of 17 with malabsorption of various types, 16 with large intestinal carcinoma, 11 with amebiasis, 30 with pernicious anemia, 22 with autoimmune thyroiditis, 22 with systemic lupus erythematosus, 21 with rheumatoid arthritis, 35 with scleroderma and 20 normal healthy subjects) were studied. Sera from the ulcerative colitis patients included 10 giving immunofluorescent staining of human colon mucosa, 13 staining rat colon, and 17 with hemagglutination titers of 16 or more against rat feces antigen. In contrast with the immunofluorescence reactions against human and rat colon, hemagglutinating antibodies to rat colon antigens were no greater in incidence than in the 194 control sera. The positive sera reacted with other parts of the gastrointestinal tract, and no evidence of colon specificity was obtained. In addition, they were not specifically cytotoxic to human colon mucosa in tissue culture. Three ulcerative colitis sera contained antibodies against rat gastric parietal cells, 1 reacted with thyroid cytoplasm and none reacted with nuclei, adrenal or thyroid colloid. It is suggested that the autoantibodies that react with human intestinal mucosa are not themselves responsible for mucosal damage, but may reflect underlying cellular activity by autoimmune lymphoid cells.

7304 INTESTINAL MICROFLORA IN NONSPECIFIC ULCERATIVE COLITIS PATIENTS BEFORE AN AFTER TREATMENT. (Rus.) Il'khamov, A. I. (Uzbek Inst. Postgrad. Med., USSR), B. F. Kadyr and T. D. Guliamov. Med. Zh. Uzbek. (2):25-27, 1967.

5 EXPERIENCES WITH NEOESERINE IN THE
FUNCTIONAL DIAGNOSIS OF THE PANCREAS.

r.) Kaczmareck, H. (Wittenberg Hosp.,
many). Z. Aerztl. Fortbild. (Jena) 61(3):
-134, 1967.

neostigmine test was given to 25
ients, 14 women, and 11 men, 9 with pan-
atitis, 3 with carcinoma of the pancreas, 1
n gallbladder carcinoma, 3 viral hepatitis
es, 5 having cholecystitis, and 4 in terminal
ndice. Freostigmine (1 mg) was inj. i.m. in
fasting patient at 8 A.M. after samples were
en for the determination of serum and urinary
lase levels, normal values, 8-32 and 16-128
lgemuth units, resp. Amylase conc. were
sured in serum and urine 30, 60, 90, and 120
after inj. of neostigmine. A pathological
ication occurred when (1) serum and urinary
lase increased over the normal values, (2)
um and urinary amylase increased or decreased
n elevated production of pancreatic amylase,
urinary amylase increased over the normal
ues with simultaneous fall of serum amylase,
normal amylase production with decrease
ow normal in serum and urine. Of the 9
ients with pancreatitis 7 showed positive
ction to the test (elevation of urinary and
um amylase above normal ranges) and 2 showed
ative reaction (amylase levels within normal
ges); 3 cases of carcinoma gave negative
ponses to the test, 1 case of gallbladder
cinoma had a negative test; of 3 patients
n viral hepatitis 2 were positive and 1 was
otful; of 5 cases of cholecystitis, 2 were
itive, 2 negative and 1 doubtful; 4 with
minal jaundice showed 1 positive, 2 negative
1 doubtful result. The max. amylase levels,
ardless of the results, occurred at 60 and 90
after neostigmine admin. The diagnosis of
creatitis was secured by medical history,
nical observation, laboratory examination,
finally by observation at operation and biopsy.
other pathologies were also carefully estab-
hed. No complications arose in the applica-
n of this test; no influence could be found on
diac rate, circulation time, or blood pressure.

6 CAPILLARY MICROSCOPY. ABNORMALITIES
IN CYSTIC FIBROSIS, CONGENITAL HEART
EASE, AND MONGOLISM.

(E.) Higashino, S. M.,
A. J. Moss (U. California Sch. Med., Los
eles). Amer. J. Dis. Child. 113(4):439-443,
7.

end-row capillaries of the nailbeds were
mined microscopically in 110 children and
lescents, of whom there were 20 normals
16 yr. old) and 23 with cystic fibrosis
20 yr. old). Using the classification of
st, morphology was considered to be normal if
e than 85% of the capillaries were composed
good and/or poor hairpin forms. Morphology
was assumed to be abnormal if the proportion of abnormal forms (which included single and double twist forms, Y-shaped, bizarre and tiny immature forms) exceeded 15%. The presence of horizontal subpapillary plexus was considered the most primitive form, also abnormal, and was categorized separately. Of 20 normals, 19 had more than 85% normal forms; the single exception had 82% normal forms. A horizontal subpapillary plexus was seen in only 2 children, both 3 yr. old. Of 23 with cytsic fibrosis, 19 (83%) had abnormal morphology and, of these, 9 (40%) had horizontal subpapillary plexus. The latter tended to increase with increasing severity of the disease. Of 14 classified as excellent, good or mild, 10 had abnormal morphology with horizontal subpapillary plexus in 2; of 9 with moderate or severe disease, all 9 had abnormal morphology and 7 had horizontal subpapillary plexus. Cyanosis was associated with an insignificant increase of abnormal capillary morphology, but with a significantly increased incidence of horizontal subpapillary plexus, thereby suggesting that local hypoxemia may have been a causative factor.

7307 THE COMPOSITION OF RECTAL MUCUS IN CYSTIC FIBROSIS.

(E.) Roelfs, R. E. (Univ. Hosp., Omha, Nebr.) G. E. Gibbs and G. D. Griffin. Amer. J. Dis. Child. 113(4): 419-421, 1967.

L-Fucose, mannosamine, galactosamine, glucosamine, N-acetylmannosamine, N-acetylgalactosamine and N-acetylneuraminic acid (methyl ester) in the hydrolysates of rectal mucus specimens were assayed by gas chromatography. The sugars were protected from decomposition during the course of chromatography by converting them to their trimethylsilyl ethers before inj. into the gas chromatograph. Rectal mucus specimens were obtained with a special triple-lumen tube from 11 cystic fibrosis patients (2-15 yr. old) and 19 nonfibrocystic control subjects (1-14 yr. old; 6 of whom had pneumonia, 2 nutritional anemia, 3 pharyngitis and croup, and 1 each spina bifida, fracture, ethanol intoxication, mental retardation, malabsorption, intertrigo, neck tumor and tonsillar hypertrophy). Thirty analyses were done for each compound. A significant increase in the content of fucose was found in mucus from cystic fibrosis subjects. The methyl group of L-fucose projects outward and is more hydrophobic than the CH_2OH groups in hexosamines; this causes a lowered aqueous solubility of cystic fibrosis mucus as compared to nonfibrocystic mucus, and may contribute to the higher viscosity of cystic fibrosis mucus. There was also a possibly significant difference in the L-fucose/N-acetyl-neuraminic acid ratio.

7308 ADULT MUCOVISCIDOSIS.

(E.) Goodman, D. H. (Good Samaritan Hosp., Phoenix, Ariz.). Ann. Allerg. 25(4):224-228, 1967.

Three patients 18, 23 and 51-yr.-old with a history of nasal polyposis in early childhood, all had markedly elevated levels of Na and Cl (130.9-197.0 mEq/liter) in the sweat. The 23-yr.-old Caucasian male exhibited all of the classical manifestations of mucoviscidosis: nasal polyposis, chronic sinusitis, advanced obstructive ventilatory disease of the lungs, duodenal ulcer, pancreatic insufficiency and digital clubbing. A 51-yr.-old white female had nasal polyposis, duodenal ulcer and bronchiectasis. The 18-yr.-old female exhibited a partial form of the disease: nasal polyposis, first observed at 4 yr. of age, chronic sinusitis and persistent cough. Detailed results of pulmonary function tests are given for each patient. Quantitative analysis of sweat Cl should be performed on any adolescent or adult with a history of nasal polyposis in childhood. Mucoviscidosis can exist in a relatively mild form, and pancreatic insufficiency is not an essential feature in every case. Approx. 15% of patients with mucoviscidosis have concurrent respiratory tract allergy, and 10% have nasal polyposis.

7309 RAPID METHOD FOR THE DETECTION OF CYSTIC FIBROSIS OF THE PANCREAS IN CHILDREN.

(E.) Saggers, B. A. (Queen Mary's Child. Hosp., Carshalton, Surrey, England), D. Lawson, J. Stern and A. C. Edgson. Arch. Dis. Child. 42(222):187-189, 1967.

A new method for measuring the Na conc. of unstimulated parotid saliva using a microdual Na electrode (which is a modification of a Jena microdual-pH electrode) is described. The electrode was placed in the upper region of the cheek next to the second molar tooth at the opening of Stensen's duct, and sterilization of the electrode was effected by wiping it with a pad soaked in 70% isopropanol. Normal subjects (31; 1-48 yr. old) gave parotid saliva Na levels from 3-15 mEq Na/liter (mean value, 5.9); cystic fibrosis heterozygotes (10; 25-49 yr. old), all of whom were parents of known homozygotes, had values between 4.5-12.0 mEq Na/liter (mean value, 5.69) and cystic fibrosis homozygotes (15; 1-19 yr. old) gave Na levels from 12-52 mEq Na/liter (mean value, 27.2). The difference between normals and cystic fibrosis homozygotes was highly significant. Approx. 4% of the values fell in an overlap range of 12-15 mEq Na/liter. No correlation was found between parotid saliva Na levels and ages of the test subjects. Cystic fibrosis heterozygotes did not show any significant difference in pNa values from normals. Studies are underway to adapt the size of the electrode for use in neonates.

7310 THE ABSORPTION OF HEMOGLOBIN BOUND IRON IN CASES OF MUCOVISCIDOSIS.

(Ger.) Strahm, H. W. (U. Clin. Bern, Switzerland). Arch. Kinderheilk. 175(3):270-279, 1967.

The absorption of Fe was studied in 13 children with mucoviscidosis, and in 13 other children of the same age distribution without infectious disease, anemia, or gastrointestinal disorder, as controls. The iron was ^{59}Fe incorporated in hemoglobin, admin. p.o. in doses proportional t body wt. The radioactivity of the hemoglobin was determined as well as that of the 5-day stoc collection. The 13 patients with cystic fibrosis had an av. Fe absorption of 19.5% (4.8-60.4%) and the 13 controls, 9.5% (0-35%). The distributions were such that the av. were not statistically significant. When the 3 highest absorptions were omitted from the results of these with fibrosis, the av. for the group became 12.8% which is within the normal range and therefore not significant. The absorption of ionic Fe and Fe bound to hemoglobin (as heme) has been measured and found to be the same in normal individuals. The higher hemoglobin conc. of those with pancreatic fibrosis (as compared to the normal) is still unexplained.

7311 ASSOCIATION OF PANCREATIC INSUFFICIENC AND CHRONIC NEUTROPENIA IN CHILDHOOD.

(E.) Burke, V. (Roy. Child. Hosp., Melbourne, Australia), J. H. Colebatch, C. M. Anderson and M. J. Simons. Arch. Dis. Child. 42(222):147-157, 1967.

Of 19 children presenting initially with 1 of th 2 main features of the title syndrome, 11 (5 boys, 6 girls) were found to have both features, e.g., 5 of 11 presenting with neutropenia and 6 of 8 presenting with malabsorption. Gastrointestinal features included steatorrhea, with a daily fat excretion of more than 5 g, in 9 of 11 patients; in these, fat globules were seen at some time on microscopy of the stools. In all patients with pancreatic insufficiency, there was no more than a trace of activity of trypsin, lipase or amylase in duodenal contents, and no particular enzyme was differentially reduced. In each of 3 in whom a biopsy of the small intestine was performed, mild inflammatory changes with blunting of the villi were seen in the mucosa. Giardia lamblia infestation was present in 1 case when duodenal biopsy was obtained. Hematological features included a persistently low neutrophil count, ranging from 0-200 cells/mm3 and contributing only 2-3% of the total WBC, in 7 of 11 children. Thrombocytopenia occurred in only 2, but anemia, which was corrected by admin. of Fe, occurred in all but 3 patients. Of 8 in whom bone-marrow aspirations were performed, 6 showed a deficienc of myeloid elements (bone-marrow hypocellularity and 1 of these also had megakaryocyte deficiency Radiological features of metaphysial dysostosis were found in 3 patients, while congenital megacolon also occurred in 1 case and in a cousi of 3 patients who were siblings. Familial studies showed that the father of 1 patient had mild neutropenia, but the mother's WBC were normal; another case had a sister with neutropen This syndrome of chronic neutropenia and pancreatic insufficiency is rare, but after excluding patients with cystic fibrosis, it

pears to be the most common cause of pan-
eatic insufficiency in childhood.

12 TREATMENT OF PANCREATIC EXOCRINE
INSUFFICIENCY: I. *IN VITRO* LIPOLYTIC
TIVITIES OF PANCREATIC LIPASE AND FIFTEEN
MMERCIAL PANCREATIC SUPPLEMENTS. (E.)
ulian, B. B. (Hahnemann Med. Coll., Philadelphia,
.), L. M. Singh, A. O. Mansfield, F. W.
irent and J. M. Howard. *Ann*. *Surg*. 165(4):
4-570, 1967.

pase activity was measured by the Johnson-
ckus modification of the Cherry-Crandall
thod. In addition to commercial preparations
onvertin, Converzyme, Cotazym, Dactilase,
zypan, Festal, Kanulase, Kutrase, Kuzyme,
pan, Pancreatin (X 1), Panteric Granules,
e-Gestive, Uticon, Viokase), 2 conc. lipase
tracts were used for comparison (crude pork
ncreatic lipase and Lipase P). Reaction
xture consisted of 3 ml distilled water, 2 ml
ive oil emulsion, 0.5 ml M/15 phosphate buffer
H 7.2), 1 ml lipase soln.; was incubated at
° for 18 hr.; reaction was terminated by
dition of 40 ml ethanol-ether (9:1) mixture.
mples and blanks were titrated to pH 10.65
th NaOH and the difference between the 2
lues was expressed as the Cherry-Crandall
pase U. Results with hog pancreatic lipase
d canine pancreatic juice showed that
drolysis of olive oil substrate under these
nditions was directly proportional to the
zyme conc., up to 10 U. On an equal wt.
sis, the highest hydrolytic activity was
own by Cotazym, Lipan, Panteric Granules, and
okase; lowest by Convertin, Kanulase, Kutrase,
zyme. Human pancreatic lipase from a patient
th a pancreatic fistula contained 160 U/ml.
nety-six g Festal or 34 g Cotazym would be
quired to completely replace the pancreatic
cretion in 1 day. The bile salt, Na tauro-
olate, increased lipase activity, but the
fect was diminished at high conc. All
eparations were inactivated at pH 2, and
owed max. activity at neutral and alkaline pH.
pase activity was increased slightly (5.5-6.8 U)
the presence of human serum albumin (10 mg/ml).
ypsin (10 mg/ml) slightly decreased lipolytic
tivity (7.3-5.9 U/ml). It is suggested that
e addition of bile salts to these preparations
d enteric coating might be advantageous.

3 TREATMENT OF PANCREATIC EXOCRINE
INSUFFICIENCY: II. EFFECTS ON FAT
SORPTION OF PANCREATIC LIPASE AND FIFTEEN
MMERCIAL PANCREATIC SUPPLEMENTS AS MEASURED BY
31 TAGGED TRIOLEIN IN THE DOG. (E.) Giulian,
B. (Hahnemann Med. Coll., Philadelphia, Pa.),
Mitsuoka, A. O. Mansfield, J. E. Trapnell,
A. Seddon and J. M. Howard. *Ann*. *Surg*.
(4):571-579, 1967.

n and accessory pancreatic ducts were ligated
d divided without interruption of blood supply
to gland or duodenum. Because of effects on fat absorption, in latter operations a complete separation of the head of the pancreas from the duodenum was performed and a leaf of omentum inserted between and wrapped around the duodenum, providing reliable exocrine occlusion. Absorption studies were performed over 3 mo. *In vivo* studies of ^{131}I-triolein uptake were made before and after ligation and division of pancreatic ducts. Effects of 15 pancreatic supplements (Convertin, Converzyme, Cotazym, Dactilase, Enzypan, Festal, Kanulase, Kutrase, Kuzyme, Lipan, Pancreatin (X 1), Panteric Granules, Pro-Gestive, Uticon, Viokase) and of 2 lipase preparations (crude pork pancreatic lipase and Lipase-P) were measured in respect to: normal preoperative uptake; control postoperative uptake; uptake within 4 days of the latter, with addition of pancreatic supplements. The different preparations exhibited wide variation in effects. *In vivo* results generally correlated with previous *in vitro* studies. Best results were obtained with Cotazym, Converzyme, Festal and Panteric Granules, the latter 3 being enteric-coated. The other preparations showed little if any ability to increase fat digestion as measured by this method. No single preparation always caused an increase in uptake, but preparations giving 'good' results usually exerted a beneficial effect on lipid absorption.

7314 REGENERATIVE AND COMPENSATORY PHENOMENA IN PANCREAS AFTER RESECTION. (Rus.)
Polyak, R. I. (Med. Inst., Chernovtsy, USSR). *Biull*. *Eksp*. *Biol*. *Med*. 62(12):95-99, 1966.

Dogs were divided into 5 groups according to type of pancreatic resection: Group 1, 16 animals, resection of the terminal portion of the gland; Group 2, 12 animals, resection of the central portion of the pancreas (corresponding to the head of the gland in man) with ligation and resection of the excretory duct; Group 3, 9 animals, resection of the central portion as well as some of the terminal portion; Group 4, 12 animals, removal of the pancreas with preservation of the portion closest to the duct; and Group 5, resection of the pancreas with subsequent suture of the stump into the lumen of the jejunum. Immediately after surgery, the blood sugar content was elevated to 160-200 mg%, and after the third-fourth day it decreased to 120-140 mg%. Other blood parameters were normal. After double loading with sugar (2 g glucose/kg body wt.), the graph of blood sugar did not always resemble its initial form. In general, glycemia curves during the postsurgical period differed from the basic, initial curve by a greater increase after the second glucose loading, and a slower decrease thereafter; this is indicative of functional insufficiency of the islands of Langerhans. However, after surgery the glycemic curves approached normality, and this was evidence of compensatory and regenerative capacity of the islands of Langerhans in the residual pancreas. In Group 2 there were immediate postsurgical complications (peritonitis, pancreaticonecrosis). A study of pancreatic exocrine function showed that removal of the final portions of the organ were not accompanied by a disturbance of the ability to absorb and assimilate fats and proteins. In animals of Groups 2 and 3 there was evidence of disturbed absorption and digestion of fats and proteins; this was shown by the excretion of many drops of neutral fats and undigested muscular fibers in the feces. In animals of Group 5, fats and proteins were poorly metabolized and the feces were markedly altered (light in color, liquid in nature, larger in amount with a large amount of undigested muscular fibers and fat droplets); this condition improved later. This is also evidence of many compensatory and regenerative processes. The most unfavorable results accompanied subtotal resection, i.e., fatty necrosis (causing death in 3 animals), purulent inflammation, and cyst-like cavities in regions of focal destruction of survivors. There were atrophic changes and the development of connective tissue in the residual pancreas (this increased with time) in animals of Groups 2 and 3; thus, pancreatic function was not restored. In dogs in which the pancreatic stump was peritonized with omentum and then isolated from the intestinal lumen, there was evidence of pronounced atrophy of the acinar tissue and proliferation of connective tissue 2-3 mo. after surgery. Dogs with a pancreatico-intestinal anastomosis showed only slight swelling of the interlobular connective tissue layers and an increase in acinar tissue. This demonstrated the compensatory capacity of the pancreas.

7315 PHARMACOLOGIC STUDY OF RESIDUAL EXOCRINE PANCREATIC FUNCTION FOLLOWING CEPHALIC DUODENOPANCREATECTOMY. (EXPERIMENTAL CLINICAL STUDY.) (It.) Mezzacapo, B. (Civil Hosp., Brescia, Italy). Minerva Chir. 22(1): 42-48, 1967.

In 3 men (aged 37, 50 and 52 yr.) in whom the remaining pancreas was stimulated by i.v. inj. of secretin (2 of 3) or i.m. inj. of neostigmine (1 of 3), 17 mo., 18 and 20 days, resp., after amputation of the head of the gland in the presence of pancreatic carcinoma, exocrine pancreatic function was entirely within normal limits. In a fourth man with pancreatic cancer (aged 53 yr.), who was operated in the same way in the presence of generalized sclerosis of the pancreas (found at the time of operation), a similar response to secretin could not be elicited 9 mo. after surgery. It is concluded that residual pancreatic exocrine function after this type of surgery can be sufficient to meet normal digestive demands in the absence of stenosis at the orifices or parenchymal damage due to recurrence in situ or chronic pancreatitis. It is also concluded that the operation of choice terminates with a pancreatic-jejunal anastomosis, further reinforced by muco-mucosal suture.

7316 ADIPOSE ATROPHY OF THE EXOCRINE PANCREAS. (E.) Walters, M. N-I. (U. Western Australia, Perth). J. Path. Bact. 92(2):547-557, 1966.

Blocks of human tissue, from head, body, and tail of pancreas obtained from 200 almost consecutive necropsies on adults, were fixed with 4% neutral formaldehyde and impregnated with paraffin. Experimental rats (150-300 g) had the duct to the splenic segment ligated within 1 cm of the splenic hilus and 260 mice received introduction of reovirus type III pancreatitis. Experimental biopsies were treated as above. Of 200 necropsies, 60% showed significant fatty replacement of the pancreas, while 30% showed this to a minor degree. The lesion was commonly associated with diabetes mellitus, hepatic and cholecystic disease, obesity, degenerative vascular disease, or dietary insufficiency, although no conclusive etiologic associations were made. Studies on animals suggested several likely sources of fatty tissue: mesenchymal lipoblasts, cells of reticulin stroma, mononuclear cells derived from lymphoreticular taches laiteuses, degenerated acinocytes, multiplication of existing pancreatic fat deposits, and possibly a totipotent ductular reserve cell. Infiltration usually followed acinocytic atrophy and ductular-cell proliferation. It is suggested that some form of ductal obstruction may be the major pathological basis of adipose replacement of the exocrine pancreas despite several possible modes of lipogenesis available to it. Regardless of cause, in the presence of acinocytic atrophy, adiposity remains the final common morphological pathway available to the pancreas.

7317 ALLOTRANSPLANTATION OF THE PANCREAS IN DOGS. (E.) Ota, K. (Tokyo U. Sch. Med., Japan), S. Mori, M. Nobori and T. Inou. J. Surg. Res. 7(5):207-214, 1967.

Of 60 dogs used, 30 were donors and 30 recipients (10 controls received no anti-rejection drugs). After allotransplantation (modified after DeJode), transfusion was with donor blood and postoperative antibiotic therapy consisted of i.v. admin. of 250 mg Signemycin (83 mg oleandomycin phosphate plus 167 mg tetracycline hydrochloride per vial) daily for 3 days. Azathioprine was admin. i.v. at 6 mg/kg on the day of operation and this dose was repeated p.o. daily. Functioning of pancreas transplant was evaluated by the blood glucose method of Hagedorn and Jensen. The controls lived an av. of 10 days; the azathioprine group 22 days. Death was caused by rejection in 6 controls and 6 azathioprine dogs. In 5 of these 12, the last fasting blood glucose level was greater than 150 mg/100 ml. This suggests that hyperglycemia is a terminal, rather than initial, sign of rejection. Histological observation showed the control group to be characterized by acute rejection resembling acute pancreatitis. Chronic

jection manifested by interstitial fibrosis
s found in the azathioprine group. It is
ncluded that azathioprine is effective in
ppressing the acute rejection process but was
able to prevent fibrosis.

18 A METHOD FOR THE DETERMINATION OF
TRYPSIN AND CHYMOTRYPSIN IN FECES BY
ANS OF AMINO ACID-P-NITROANILIDES. (Ger.)
llig, F. (U. Heidelberg, Germany) and W.
rber. Z. Gastroent. 5(1):33-36, 1967.

ces (2 g) were homogenized in 5- or 10-times
lution with buffer soln. at 0°C. Only
mples of the same or preceding day were used.
r the determination of trypsin, 0.5 ml of the
ool homogenate was mixed with 5 ml Tris
ffer, pH 7.8, containing 0.025 M $CaCl_2$ at
°C; the reaction time was 15 min. at 25°C in
waterbath with the addition of 0.1 ml 0.55 M
α-benzoyl-arginine-p-nitroanilide as substrate;
e reaction was terminated with the addition
2.8 ml 40% trichloracetic acid. For the
termination of chymotrypsin, 0.5 ml of the
ool homogenate was mixed with 3 ml of Tris
ffer, pH 7.5 containing 0.66 M $CaCl_2$ at 25°C;
action time was 1 hr. in a water bath at 25°C
ter addition of 0.05 ml 0.35 M N-succinyl-L-
enylalanine-p-nitroanilide as substrate; the
action was terminated with 1.8 ml 40% tri-
oracetic acid. In both reactions, the pro-
ct, p-nitroaniline, cannot be measured
rectly by photometry due to suspended matter;
itroaniline is converted into a red azo dye
ter precipitation of suspended solids by
chloracetic acid; the azo dye is then measured
photometry at 546 nm. Determinations of
ypsin and chymotrypsin were made in samples
om 64 subjects with normal pancreatic glands
no history of pancreatic disease. A
fference in fecal conc. of the enzymes accord-
to sex or age did not occur. Trypsin
μg) and 74 μg of chymotrypsin/g feces
t wt.) are regarded as the lower limits of
normal range. The arithmetic mean of the
ypsin determinations was 167 μg/g stool (wet.
), and of the chymotrypsin measurements,
μg/g stool (wet wt.). Samples of the same
ol preparations stored at 5°C and at 25°C had
y a 2% loss in trypsin activity after 5 days
5°C but a 63% loss after 5 days at 25°C. The
s of chymotrypsin activity after 5 days at
C was over 80°. The two substrates are
yme-specific when no enzyme inhibitors are
sent.

5 ACUTE PANCREATITIS ASSOCIATED WITH AN INTRALUMINAL DUODENAL DIVERTICULUM.

) Nance, F. C. (Louisiana State U. Sch. Med.,
Orleans), J. Cocchiara and J. L. Kinder.
troenterology 52(3):544-547, 1967.

l-yr.-old Negro man complained of mild inter-
tent epigastric pain and occasional nausea
3 mo., with no history of excessive alcohol
ake. Physical examination was normal, there
no evidence of wt. loss, the abdomen was
with no palpable masses and initial labor-
y studies were normal. On the fifth day he
plained of severe epigastric pain, nausea
vomiting and revealed minimal epigastric
derness and a soft abdomen. Studies showed:
17,850/ml with a shift to the left of poly-
phonuclear cells; hematocrit 48%; serum
lase 280 Somogyi U; lipase 4.4; serum Ca
mEq; serum P 2.72 mg/100 ml. Subsequent
and P levels were normal. Clinical diagnosis
pancreatitis was made. Symptoms subsided
values returned to normal on conservative
rapy. On day 45, he had severe epigastric
n, nausea and vomiting; there was moderate
gastric tenderness but a soft abdomen;
perature was normal; serum amylase was
vated to 310 U. Symptoms continued for 24 hr.,
siding on conservative therapy. Initial X-ray
upper gastrointestinal tract was normal except
a spasm of the duodenum, attributed to pan-
atitis. A second X-ray showed an intraluminal
erticulum in the second and third portion of
duodenum, and this filled with Ba. The
ximal duodenum was enlarged and gastroscopic
mination and cholecystogram were normal.
aratomy revealed an enlarged duodenum with a
tinct decrease in size in the area of the
ulla of Vater. An anterior duodenotomy per-
med at this point revealed a large intra-
inal diverticulum extending distally from
ampulla of Vater and attached to the lateral
denal wall. The diverticulum was excised
m both attachments, the mucosal defect re-
red, the duodenum closed transversely. The
creas was firm, swollen and indurated; gall-
dder, common bile duct and biliary tree were
mal; the pancreatic duct could not be vis-
ized. Recovery was uneventful.

6 SELECTIVE SURGERY FOR RELAPSING PANCREATITIS.

(E.) Keddie, N. C.
rk Hosp., Manchester, England). Brit. J. Surg.
2):106-109, 1967.

nsduodenal sphincterotomy was performed and
y sutures inserted into the margins of the
ision in the sphincter to hold it open. The
fice of the pancreatic duct was sought below
orifice of the common bile duct. A catheter
inserted into the orifice for 2-3 cm and
l 50% Hypaque soln. was inj. via the catheter.
ssure of inj. was reduced by the high resis-
ce to flow within the catheter. Pancreato-
ms were carried out on patients undergoing
surgery for relapsing pancreatitis (35 of 200). In 32 of 35, sphincterotomy was the initial operation. Relief on the basis of sphincterotomy could be predicted on the basis of X-ray appearance correlated with follow-up of 1-10 yr. Prediction was correct in 75%. One died from postoperative pancreatitis. Pancreatographic findings were: normal (6); dilatation of main duct (8); tortuosity and multiple narrowing of main duct (2); incomplete filling of main duct (9); abnormal filling with pooling of dye (8); acinar filling (2). Only the latter 2 groups yielded successful predictions. Surgical procedures recommended for the above findings were, resp.: care to exclude other diseases; sphincterotomy; Puestow procedure; sphincterotomy and excision of tail with retrograde draining into loop of jejunum.

7337 MANAGEMENT AND PROGNOSIS OF ACUTE PANCREATITIS.

(Ger.) Asang, E. (City Hosp., Munich, Germany). Lebensversicher. Med. 19(3):59-63, 1967.

Comparison is made between the treatment of acute pancreatitis in two periods: yr. 1954-1958 inclusive, and 1959-1963 inclusive. The treatment during the 2 periods was basically the same, the so-called active conservative therapy of Nordmann. The chief difference was the use of Trasylol in the second period. Mortality in the first period was 39.5% and in the second, 9.9%. However, when primary and untimely laparotomies were performed on patients with pancreatitis mortality in the first period was 65.5% and in the second period, 63.6%. This indicates the extreme danger of general upper abdominal surgery during acute pancreatitis. The performance of primary conservative right-sided operation in the first period resulted in a mortality of 33.3%, in the second period of 3.6%. These improvements may not have been entirely due to Trasylol because the incidence of complications in cases of pancreatitis decreased from 21.5% in the first period to 11% in the second. The incidence of postoperative pancreatitis in a total number of 4786 stomach and biliary operations 1955 in the first and 2831 in the second period declined from 7.2% to 5.8% and the mortality rate from 1.5% to 0.4%.

7338 SELECTIVE PROPHYLAXIS OF POSTOPERATIVE PANCREATIC NECROSIS.

(Ger.) Hoferichter, J. (U. Erlangen-Nuremberg, Germany). Chirurg 38(5):233-236, 1967.

Postoperative hemorrhagic necrotizing pancreatitis a serious complication of upper abdominal surgery almost without exception terminates fatally. Routine use of proteinase inactivators is not possible: (1) Postoperative necrosis of the pancreas is relatively rare. (2) The action of proteinase inactivators is not sufficiently known. (3) The financial outlay, on account of the high dosages required, is considerable. A selection of patients is necessary. The indications for this are: (1) Trauma of the pancreas, (2) Possibility of reflux of bile or an intraglandular activation of enzymes. These indications are present in all partial resections of the pancreas for whatever cause, in manipulations of the papilla, and in any operative or other manipulation of the biliary tract which might result in reflux into the pancreas, as well as in cases of fulminating or florid pancreatitis. The prophylaxis must be begun during the operation with 50,000 U of Trasylol. During the course of the operation and for 2-3 days afterward 100,000 U/day are admin. In 1000 upper abdominal operations in the last 3 yr., in which selective prophylaxis was practiced, no case of necrotizing pancreatitis occurred. In 1500 upper abdominal operations in the 7-yr. period before that in which 1500 such operations were done without prophylaxis, there were 9 instances of fatal necrotizing pancreatitis.

7339 THE INFLUENCE OF HYPOTHERMIA UPON THE DEVELOPMENT OF EXPERIMENTAL PANCREATITIS. (Ger.) Eichelter, P. *Klin. Med. (Wien)* 22(4): 179-187, 1967.

A total of 50 dogs (9-27 kg) were used to study the effects of hypothermia upon experimental pancreatitis. The dogs were fasted for 12 hr., anesthetized and kept under artificial respiration. The duodenum was transected at the pylorus and 4 cm distal to the duct of Santorini; both ends of the duodenum were closed and the continuity of the gastrointestinal tract was reestablished by anastomosis of the pylorus with the distal duodenum. The common bile duct was doubly ligated. A shunt between the carotid artery and jugular vein through a long polyvinyl catheter, placed in water (10-15°C), reduced the rectal temperature of 22 dogs in less than 2 hr. to 28°C, which was maintained for an av. of 19 hr. Three of these dogs had body temperature of 28°C within less than 4 hr. after formation of the blind duodenal loop. The temperature of the other 19 dogs was reduced from 4.5-10 hr. after construction of the blind loop. All 13 of the control dogs died in 12-31 hr. of acute hemorrhagic pancreatitis. The av. value of diastase in the peritoneal fluid was 2245 U. The 3 dogs with temperature reduced within less than 4 hr. did not develop pancreatitis. These dogs were reoperated and the gastroduodenal region reconstructed and the ligatures removed; their temperature was brought back to normal by placing the polyvinyl shunt tube in water at 42°C, after which they received saline infusions and antibiotics. These dogs survived for 50, 67, and 72 days until they were killed for examination. These animals had 276-310 U of diastase in the peritoneal fluid. Of the 19 dogs with a rectal temperature of 28° reached 4.5-10 hr. after surgery, 11 lived longer than 2 days, 6 from 9-72 days before being sacrificed. Diastase values were intermediate. Nine dogs in this group died of complications such as wound infection, pneumonia, and pulmonary emboli.

7340 NATURAL VARIATION IN EXPERIMENTAL HEMORRHAGIC PANCREATITIS. (E.) Williams, L. F., Jr. (Boston City Hosp., Mass.) and J. J. Byrne. *Surg. Gynec. Obstet.* 124(3): 531-535, 1967.

The incidence of severe hemorrhagic pancreatiti as well as death was compared between a group o 88 adult mongrel dogs with closed duodenal loop obstruction with biliary tract exclusion (Pfeff preparation) and a group of 59 dogs with main pancreatic duct infusion with 5 ml of duodenal loop fluid obtained from a Pfeffer preparation infused at less than 600 ml of H_2O. Since both groups are identical in all respects, pancreati duct infusion allows evaluation of the hemorrha pancreatitis component of the Pfeffer preparati in the absence of strangulation obstruction. Analysis of comparative data between the 2 grou revealed a variation in the degree of hemorrhag pancreatitis that was related not only to the nature of the infusate, but also to an undefine normal variation in response by any given dog. Severe changes occurred in 67.6% of the Pfeffer group dogs and in 67% of the pancreatic duct infusion preparations. The death rate at 24 hr in pancreatic duct infusion dogs was 35.8%, whi was statistically no different than results in the Pfeffer dogs. There was a tendency for mor severe pancreatitis to occur in the pancreatic duct infusion dog when the Pfeffer dog had severe pancreatitis, but the relationship was n linear. It is suggested that the presence of individual animal variation previously referred to, at least in the dog, makes evaluation of therapy when based upon small numbers of dogs difficult and frequently meaningless.

7341 POSTGASTRECTOMY PANCREATITIS. EXPERIMENTAL ASPECTS. (Sp.) Filgueira, L. (Fac. Med., Montevideo, Uruguay), U. Larre Borg and A. Del Campo. *An. Fac. Med. Montev.* 50(3/4 278-286, 1966.

Four groups of dogs were subjected to partial gastrectomy with a precolonic gastroenteroanastomosis from the lesser to the greater curvatur Group 1 received no other treatment; Group 2 wa also subjected to traumatization of the pancrea Group 3, to total occlusion of the afferent loo Group 4, to partial occlusion of the afferent loop. At 48 hr., the pancreas was normal in 9 of 9 dogs in Group 1, as were values for serum pancreatic U, determined by Wohlgemuth's method In Group 2, 10 of 11 had developed acute pancreatitis (hemorrhagic in 4 of 10) and serum pancreatic U were above normal levels in 2 of 8 studied from this point of view. In Group 3, 9 of 12 had developed pancreatitis (acute in 6 of 9; hemorrhagic in 4 of 6); serum pancreatic U were above normal levels in 4 of 7 studied from this point of view; 5 of 12 died within 24 hr. and 2 of 12 were in a severely deteriorated sta In Group 4, 4 of 10 had developed acute pancreatitis (hemorrhagic in 2 of 4) and the pancre were normal in 6 of 10. Serum pancreatic U wer above normal levels in 1 of 5 studied from this

t of view. It is concluded that trauma to
pancreatic parenchyma and occlusion of the
rent loop should both be considered as po-
ially serious risks during gastric surgery.

7355 CLINICAL STUDIES ON ACUTE PANCREATITIS. AN ANALYSIS OF 65 CASES. (E.) Lee, C. (Seoul Nat. U.,), W. Lee and S. S. Hahn. Korean J. Intern. Med. 10(2):109-115, 1967.

7356 THE SEPARATION OF GC-PHENOTYPES AND GC-ALLELES IN SOME DISEASES (DIABETES MELLITUS, DAMAGE TO LIVER PARENCHYMA, PSORIASIS VULGARIS). (Ger.) Jörgensen, G. (U. Gottingen, Germany) and A. Hopfer. Humangenetik 3(4): 273-276, 1967.

The functional significance of group-specific factors (Gc-factors) is wholly unknown in spite of an extensive literature. Differences in the distribution of Gc phenotypes and Gc alleles in various populations are also unknown. In the first instance their possible connection with common diseases, especially infectious diseases, comes to mind. The determination of Gc factors was done on the sera of a group of 213 patients with liver disorders, acute and chronic hepatitis and also cirrhosis. As controls a group of 1733 healthy individuals furnished sera. The technic of Hirschfeld with the aid of agar gel immunoelectrophoresis was employed. The specific anti-Gc horse sera were prepared commercially, duplicate preparations made and stained with 5% amido black soln. for purposes of lasting diagnosis and documentation. The possibilities with 2 alleles (Gc^1 and Gc^2) are 3 diploid phenotypes (1-1, 1-2, and 2-2). The number n of the control group was 1733; phenotype 1-1: observed number (0), 901 = 52%; calculated (C), 894.75 = 51.63%; phenotype 1-2: 0, 688 = 39.70%, C, 701 = 40.45%; phenotype 2-2: 0, 144 = 8.30%, C, 137.25 = 7.92%. Frequency Gc^1 allele (controls), 0.7185; Gc^2 allele (controls), 0.2815; Chi square (controls), 0.6166; $P_{(m = 2)}$ (probability with 2 degrees of freedom) about 0.75. For the sera of patients with liver disorders: n = 213; phenotype 1-1: 0, 119 = 55.87%; C, 115.7 = 54.33%; phenotype 1-2: 0, 76 = 35.68%, C, 82.6 = 38.76%; phenotype 2-2: 0, 18 = 8.45%, C, 14.7 = 6.91%. Frequency: Gc^1 allele, 0.7371, Gc^2 allele, 0.2629; Chi square, 1.343; $P_{(m = 2)}$ about 0.51. The differences between the normal group and the group with liver disease are not statistically significant.

7357 THE DISTRIBUTION OF HAPTOGLOBIN PHENOTYPES AND HAPTOGLOBIN ALLELES IN CERTAIN DISEASES (DIABETES MELLITUS, LIVER PARENCHYMAL DAMAGE, AND PSORIASIS VULGARIS). (Ger.) Jörgensen, G. (U. Gottingen, Germany) and U. Hopfer. Humangenetik 3(4):277-281, 1967.

The relationship of serum haptoglobins to liver disease was examined in 183 persons with a diversity of hepatic pathologies: 60% had acute, subacute or chronic hepatitis; 10% had cirrhosis; 15% suffered from secondary hepatitis and 5% had terminal jaundice. Control sera were furnished by 685 healthy people. Haptoglobins were determined by starch gel electrophoresis according to Smithies by the modification of von Baitsch. There were 2 Hp alleles and therefore 3 phenotypes: 1-1, 1-2, and 2-2; n = 685, the number of the controls; phenotype, 1-1: observed (0), 114 = 16.64%, calculated (C), 112.8 = 16.47%; phenotype, 1-2: 0, 328 = 47.88%, C, 330.4 = 48.23%; phenotype, 2-2: 0, 243 = 35.48%, C, 241.9 = 35.31%. Frequency: Hp^1 allele, controls, 0.4058; Hp^2 allele, 0.5942; Chi square = 0.0347; $P_{(m = 2)}$ (probability with 2 degrees of freedom) about 0.98. n = 183, the number of hepatic patients; phenotype, 1-1: 0, 37 = 20.22%; C, 33.3 = 18.17%; phenotype, 1-2: 0 82 = 44.81%; C, 89.5 = 48.91%; phenotype, 2-2: 0 64 = 34.97%; C, 60.3 = 32.92%. Frequency: Hp^1 allele, 0.4262; Hp^2 allele, 0.5738. Chi square 1.286 $P_{(m = 2)}$ about 0.53. There was no statistically significant difference between the controls and the 183 persons with hepatic disease.

7358 STUDIES ON THE PLASMIN SYSTEM IN THE LIVER OF ANIMALS WITH EXPERIMENTAL HEPATIC FIBROSIS. (Jap.) Miyamoto, A. (Osaka City U. Med. Sch., Japan). Shiritsu Daigaku Igaku Zasshi (J. Osaka City Med. Cent.) 15(11-12 599-609, 1966.

Experimental hepatic fibrosis was induced in rats by repeated i.v. inj. of egg yolk, and the fibrinolytic system and hydroxyproline content in the liver were examined at 2, 4 and 6 wk. after the beginning of egg yolk sensitization. The plasminogen activator was extracted from the liver and examined for its activity by Astrup's fibrin plate method. The fibrinolytic activity was clearly demonstrated in the 6-wk. group. The amount of hydroxyproline fluctuated almost in parallel with the titer of the plasminogen activator. Then, the localization of the fibrinolytic activity in the liver was examined by Todd and Kwaan's fibrin slide method. The activity was found to localize in the newly-formed proliferative connective tissues, but not in parenchymal cells. Addition of ε-aminocaproic acid (4 mg/ml) to the soln. to prepare a fibrin slide completely inhibited the fibrinolyt activity.

7359 CLINICAL LIVER FUNCTION TESTS IN CANINE COMPLETE LOBAR BILIARY OBSTRUCTION. (E.) Swanson, E. A., Jr. (Emory U., Atlanta, Ga.), S. W. Gray, J. E. Skandalakis and R. B. Vincenzi. Amer. J. Gastroent. 47(4): 273-279, 1967.

Of 14 dogs, 5 were sham-operated controls; 9 underwent experimental biliary obstruction of 1 lobe of the liver. Under anesthesia the abdomen was opened; the hepatic duct from the left lateral lobe of the liver was identified, doubly ligated and divided; no ligatures were placed in controls. During the postoperative period (80-120 days) all the dogs received a weekly series of liver function tests. In each experimental dog the liver with accompanying extrabiliary structures was removed at the end

the experimental period. Location and
fectiveness of ligation were confirmed by
tex inj. of the bile duct, portal vein and
patic artery. No increase in BSP retention
s observed. Serum alkaline phosphatase rose
42 King-Armstrong U within a wk., remained
evated for 1 wk. and gradually returned to
rmal after 7 wk. SGOT rose during the second
fifth wk., and an unexplained rise in con-
ols was observed in wk. 7-8. No change in
halin flocculation was observed. The
vation in thymol turbidity was not
tistically significant. All bilirubin read-
s were within normal limits, with a small
toperative rise in both sham and experimental
s. No clinical jaundice was observed. Serum
umin was raised, serum globulin lowered but
change in the albumin/globulin ratio was not
nificant. The overall picture closely
alleled that of partial biliary obstruction in
ans. Histopathology of the affected lobes
embled human biliary cirrhosis. Because of
ferences in the structure of the biliary
e and response to function tests between
ans and dogs, it is suggested that hepatic
ction cannot be evaluated by simple applica-
n of human clinical standards to dogs.

0 LIVER CELL REGENERATION AND DEGENERA-
TION AFTER LOBAR BILIARY OBSTRUCTION
DOGS. (E.) Swanson, E. A., Jr. (Emory U.,
anta, Ga.), W. S. Millians, P. C. Sotus,
E. Skandalakis and S. W. Gray. Amer. J.
troent. 47(4):280-286, 1967.

14 dogs, 5 were sham-operated controls and 9
erwent experimental biliary obstruction of 1
e of the liver. Under anesthesia the abdomen
opened; the hepatic duct from the left
eral lobe identified, doubly ligated and
ided; no ligatures were placed in controls;
incision was closed in 3 layers. At the
of the 80-120-day observation period, dogs
e reopened under anesthesia; tissue specimens
e removed from ligated and nonligated lobes
experimental animals and from corresponding
es of controls. Location and effectiveness
ligation were confirmed by latex inj. of
e ducts, portal vein and hepatic artery.
sue specimens were fixed for 24-48 hr. in
d 10% formalin with 1% $CaCl_2$. Tissue for
tological sections was embedded in paraffin
ceresin wax; 7 μ sections were made;
ining was with hematoxylin-eosin for histo-
hology, with iron hematoxylin for mitotic
nts. Specimens for 5-nucleotidase deter-
ations were prepared by the method of
hstein and Meisel, incubated in the substrate
37° for 2-4 hr. Ligation produced periportal
rous distention of large bile ducts and
liferation of small bile ducts. Bile stain-
, pyknotic nuclei, cloudy swelling and other
enerative changes were observed in the
ated lobe by 120 days. In experimental
mals the nonligated liver showed a 5-nucleoti-
e pattern similar to the normal liver, but
weaker and less evenly distributed. Ligated lobes from the same animal showed a greatly increased intensity of reaction in the cytoplasm of surviving cells, with areas of necrotic debris remaining unstained. Regeneration activity was assessed by mitotic counts of ligated and nonligated lobes at 3-4 mo. in 7 with lobar hepatic duct ligation and 3 controls. Av. number of mitoses were: 131.7 in ligated left lateral lobes; 272.3 in nonligated lobes; 95 in controls (differences were statistically significant). While some mitoses were present in normal liver (4.3%), mitotic indices rose to 10.5% in ligated and 15.8% in nonligated lobes.

7361 STUDY ON MANAGEMENT AFTER MAJOR HEPATECTOMY. (E.) Namba, Y. (Kyoto U. Med. Sch., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(6):997-1009, 1966.

Following 60-70% hepatectomy, rabbits were divided into a control and 6 carbohydrate infusion groups. Infusion was initiated 2-5 hr. after surgery and repeated every 12 hr. until death or spontaneous eating supervened. Survival rate, blood chemistry, rate of regeneration, glycogen and protein and histological studies were conducted. A survival rate of over 1 mo. was highest for the 5% fructose group (52.9%) followed by 5% glucose group (26.7%) and then the control group (8.3%). All other rabbits died before 72 hr. after surgery and never ate spontaneously. Blood glucose levels normalized for both 5% glucose and fructose groups, but the latter showed faster recovery. Both these groups manifested slow recovery of serum albumin levels. Rate of regeneration was higher in the 5% fructose group compared to the 5% glucose group, but no significant difference in liver appearance was observable in both groups at 15-22 days. After hepatectomy, the liver glycogen content was higher in the 5% fructose group than in the 5% glucose group. The protein content of residual liver remained normal in both the 5% fructose and glucose groups. In hematoxylin-eosin preparations, post-hepatectomy degenerative changes were less severe and regeneration was smoother and more rapid in the 5% fructose group. Fatty liver was shown by Sudan III stain after hepatectomy. The quantity of glycogen in the residual liver remained high postoperatively in the 5% fructose group (even on the second and third days after surgery) as compared to the 5% glucose group. It is concluded that improvement of carbohydrate metabolism after major hepatectomy is best provided by 5% fructose infusion.

7362 CHRONIC IDIOPATHIC HYPERBILIRUBINEMIA WITH PIGMENT DEPOSITION IN THE LIVER. (Ger.) Knoke, M. (U. Greifswald, Germany), H. Gürtler and J. Markert. Deutsch. Med. Wschr. 92(18):832-838, 1967.

Ten patients were observed with an intermittent jaundice of a moderate grade with a peculiar type of pigment deposition in liver cells. After medical histories were taken and the clinical examinations had been made, there was no secure basis for the presence of viral hepatitis, cholecystopathy, or hemolysis. Eight were males, 2 females with an av. age of 23 yr.; 3 were free of symptoms. The others had variable jaundice of the skin and sclera, general weakness, loss of appetite, a feeling of malaise and diffuse upper abdominal pain. All patients showed a hyperbilirubinemia of about 4.80 mg%. Bilirubinuria did not occur. The urobilinogen excretion in the urine was increased. In general, the laboratory tests were in the normal range. There was a broadening of osmotic resistence by RBC. The mechanical resistance, the direct and indirect Coombs test, the differentiation of hemoglobin were all normal. A brown, coarse-grained pigment was observed under the light microscope in the centers of the lobes and in the region of the biliary capillaries. No change in the amount of pigment was seen after 1 yr. in 5 patients; there was no indication of hepatitis or liver cirrhosis. The electron microscope showed the pigment granules to be round or oval inclusions of the cytoplasm. The electron-transparent portions resembled mitochondria. The mitochondria themselves were reduced in number and their matrix thickened. These characteristics did not fit the Dubin-Johnson syndrome and its variations. The pigment granules are in some way related to the lysosomes or the residual bodies. The general picture of the disorder would fit a lysosomal enzyme defect.

7363 STUDY ON THE ABNORMALITIES IN GLUCOSE TOLERANCE IN PATIENTS WITH LIVER DISEASE.

(Jap.) Shimizu, S. (Osaka City U. Med. Sch., Japan). Osaka Shiritsu Daigaku Igaku Zasshi (J. Osaka City Med. Ctr.) 15(11-12): 541-552, 1966.

The standard glucose tolerance test was performed on 96 patients, among whom 41 were found by liver biopsy, peritoneoscopy and liver function tests to be suffering from liver cirrhosis, 33 from chronic hepatitis, 11 from fatty liver, 7 from hepatic fibrosis and 4 from other disorders. Sixty-five of 96 patients had a blood glucose level high enough to be defined as abnormal according to the World Health Organization standard, after the admin. of 100 g of glucose. Their response to the glucose tolerance test was similar to that in the case of diabetes mellitus, suggesting the important role of the liver in the regulation of carbohydrate metabolism. Concurrent studies on the clinical history of the patients revealed that the disturbance in carbohydrate utilization was more marked in cases with a longer duration of hepatic diseases, all patients with liver cirrhosis and many with chronic damage showing this marked disturbance.

7364 DEMONSTRATION OF AMYLOID IN SPLEEN AND LIVER BY FLUORESCENCE MICROSCOPY.

(Ger.) Ludwig, G. (U. Greifswald, Germany) and L. Ahrens. Acta Hepatosplen. (Stuttgart) 14(2): 100-104, 1967.

Prepared slides of spleen and liver tissue, stained in an aqueous soln. of thioflavine-S, were examined microscopically. Amyloid showed a bright yellow-green fluorescence against a matt dull green background. The application of this method to the detection of amyloid is illustrated by 2 cases: A 58-yr.-old man with hypernephric carcinoma and stomach ulcer showed secondary amyloidosis of the liver, spleen, kidney and adrenal glands. The liver demonstrated clear pericapillary amyloidosis, especially of the intermediary and peripheral lobes; acute hyperemia and lipofuscinosis of the central lobes. A 53-yr.-old woman with primary systematized amyloidosis of liver (spotty liver), without any known basis. The liver demonstrated pericapillary amyloidosis of the intermediary zones and peripheries of the lobes. Atrophy and a small amount of fine drop-like fatty infiltration of the liver epithelium. Massive amyloidosis of the periportal arteries, as well as of the adjacent periportal connective tissue. With the exception of the brain all parenchymatous organs showed amyloid deposition by fluorescence microscopy as well as by the usual staining methods. The advantages of fluorescence microscopy for this purpose are: (1) The method is simpler, easier and more rapid than the usual technics. (2) The staining is specific for amyloid, yielding an excellent visual differentiation of amyloid from other depositions, inclusions and structures.

7365 EXPERIENCE WITH ORTHOTOPIC DOG LIVER ALLOGRAFTS.

(E.) Fonkalsrud, E. W. (U. California Sch. Med., Los Angeles), O. A. Shafey, H. Ono and W. P. Longmire, Jr. Surg. Forum 17:215-217, 1966.

A technic of orthotopic homotransplantation of the dog liver without recourse to external vascular shunts is presented. In 25 dogs, resection of the liver from the vena cava and other hilar structures followed portal venous decompression. The donor liver was removed together with the vena cava, hepatic and celiac arteries and a segment of aorta. Liver temperature was lowered to 10°-14°C. The hepatic artery and portal vein were perfused (10-15 min.) with a hypothermic soln. of Ringer's lactate, low molecular wt. dextran, heparin, xylocaine, aqueous penicillin and kanamycin. The upper end of the donor vena cava was anastomosed to the recipient's abdominal aorta. The ends of the 2 portal veins were anastomosed and the portacaval shunt left intact. For biliary decompression, the donor gallbladder was anastomosed to the duodenum. The av. period of hepatic ischemia was 57 min. Oral admin. of immunosuppressive drugs was started 48 hr. after

ration. Azathioprine (2-3 mg/kg body wt.)
prednisone (5-15 mg) were also used. Of the
dogs, one is still alive. Other deaths
luded those during first 24 hr. (10 from
cular obstruction, pulmonary aspiration and
atic ischemia); 2-7 days (4 from rejection
lung infection); 1-3 wk. (drug toxicity and
itonitis); over 1 mo. (3 dogs, 2 of which died
drug toxicity, malnutrition and infection).
longest survival time was 116 days.

STUDIES OF LIVER LOBES AUTOTRANSPLANTED
OUTSIDE THE ABDOMINAL CAVITY. (E.)
el, B. (Woman's Med. Coll., Philadelphia, Pa.),
Baldia and M. R. Dunn. Surg. Gynec. Obstet.
3):525-530, 1967.

ew technic for the autotransplantation of the
lateral lobe involving anastomosis of the
of the jugular vein to the lobar hepatic vein
p equaling 29% of the liver, to the neck
on of the dog is described. Grafts were
pared in 145 9-16 kg male and female mongrel
and were considered successful if a viable
splant with patent anastomoses was obtained
he end of the period of observation. Success
in the first 50 dogs was 8%; in the last
38%; the overall rate 24%. Grafts were
ained by perfusion of their portal beds with
rial blood at reduced pressures. Bile ducts
hepatic arteries of the grafts were ligated.
phy eventually occurred, even when vascular
tomoses remained patent. With construction
n Eck fistula, graft atrophy was halted but
phy on the nontransplanted liver was observed.
e was no evidence for significant new cell
ation in the grafts. It was suggested that
t changes after fistula construction were due
constituent change in the blood (humoral
e), since the graft changes occurred in the
nce of portal flow to the transplants and
out an apparent increase in their blood flow.
humoral mechanism may be different from that
h follows partial hepatectomy.

A DONOR IN CONTINUOUS PERFUSION OF
ISOLATED LIVER. (It.) Ruffo, A. (U.
ara, Italy), P. Rossotto, G, Motta, P.
gacopulo and R. Ferraris. Minerva Med. 57(84):
-3476, 1966.

solated swine liver was submitted to
inuous perfusion with the blood supply of a
e, living dog, derived by means of a cannula
rted into the femoral artery and returned by
s of a cannula inserted into the femoral
. Technics of this symbiotic perfusion and
ods of control are described in detail.
ogenic function was conserved throughout the
ated liver and remained within normal limits.
-formation function was also conserved in the
n, and no significant anatomical or histologic
ges were demonstrable, either during the
od of perfusion or after perfusion was
terminated. Immunobiologic studies confirmed that repeated experiments with the same host animal failed to result in its developing an immune reaction.

7368 THE USE OF AN ARTIFICIAL KIDNEY DURING THE PERFUSION OF THE ISOLATED RAT LIVER. (Ger.) Baumung, H. (U. Vienna) and M. Peterlik. Med. Pharmacol. Exp. (Basel) 16(3):275-281, 1967.

Rat liver perfusions for the study of bile production, especially those requiring periods of time greater than 20 min., with relatively small vol. of perfusion fluid (about 90 ml) run into the problem of decreasing pH in the perfusion fluid, even in whole blood, because the buffering capacity of the fluid becomes exhausted. To remedy this situation an artificial kidney (dialysis apparatus) was placed in series with the perfusion apparatus which was similar to those used by others. The artificial kidney consisted of a dialyzing tube 2.8 cm wide and 160 cm long, with connections at each end for the perfusion medium, wound about a plexiglas cylinder, the layers of the tube separated and supported by a mantle of nylon mesh; this assembly was placed in vessel having an inlet tube beneath the nylon net near the outer wall of the vessel which was in turn placed in another container of 5 liter capacity; the fluid in this container was pumped from near the surface in the container through a tube and the inlet of the vessel containing the assembly; the fluid flowed over the layers of the dialysis tubing filling the vessel and overflowing its edges back into the container. The perfusion fluid (about 60 ml) was thus dialyzed into a vol. of 5,000 ml, which was a balanced, isotonic salt soln. buffered by Na_2HPO_4 and KH_2PO_4, containing glucose, and maintained at 37°C, with a rate of flow of 3 liters/min. Tests were made with 90 cm of perfusion fluid with and without the artificial kidney; the perfusion fluid was half-heparinized rat blood and half-balanced isotonic salt soln. The pH of the perfusion medium was maintained at its original value (pH 7.4+) with the artificial kidney for a test period of 2 hr. whereas the pH of the perfusion medium without the dialyzer fell from the original value linearly to pH 6.9 in the same time period. Considerable work was done to determine the amount of ions and glucose as well as the hematocrit in the perfusion fluid at 15-min. intervals for 2 hr. with the dialyzer in circuit. The stability of all parameters is emphasized.

7369 CONTINUOUS PERFUSION OF AN ISOLATED LIVER WITH DONOR BLOOD. (Ger.) Ruffo, A. (U. Ferrara, Italy), P. Rossotto, G. Motta, G. Georgacopulo and R. Ferraris. Munchen. Med. Wschr. 109(12):620-629, 1967.

Excised pig liver of an appropriate size, with cannulations of 1) the common bile duct (the cystic duct being ligated), 2) the hepatic artery, 3) the portal vein or 1 of its tributaries, and 4) the posterior vena cava up to the level of the hepatic veins, was placed in a perfusion apparatus, maintained at 37.5°C, and connected with the extracorporeal system so that the circulating medium left the liver through the vena cava, passed through a combined oxygenation chamber and reservoir, then through a variable output pump, divided into 2 streams, one passing to the liver by means of the hepatic artery and the other passing to a larger open reservoir; from which the fluid entered the portal vein. This provided the proper arterial and portal pressures. With this system the donor blood in the perfusion medium could be that of a dog (heterologous) or that of a pig (homologous). The composition of the circulating fluid was heterologous blood, 70%, Rheomacrodex, 15% and Ringer's soln., 15%. To this was added heparin, 4 mg/100 ml blood and streptomycin, 0.1 g%. An extension of this perfusion technic with reservoirs of both homogenous and heterologous fluids, a pig liver and an anesthetized dog were placed in circuit the supply to the dog being through the femoral artery and the return from the dog over the femoral vein. In this manner the compatibility of animal and organ, animal and blood and organ and blood could be tested as well as the functional integrity of the isolated liver. Bile formation of the isolated liver av. about 0.8 for each 15-min. period (0.5-1.2 ml per 15 min. period). ^{131}I-marked Rose Bengal was excreted via the bile within the normal time limits. Contrast materials were used in the perfusion fluid to obtain normal radiographs. The perfusion between the dog and the isolated pig liver was repeated 3 times with the same dog but different livers at intervals of 15-20 days. The further inj. of 20 ml of pig liver extract at intervals of 15-20 days, 3 times into the same dog which was perfused with heterologous blood 3 times caused no immunologic reaction. Microscopically, the perfused liver appeared normal. One indication of functional integrity of the isolated pig liver was the presence of intracellular glycogen using a specific staining technic.

7370 THE LIVER AND OBESITY. (Rus.) Gorki, I. (Nutrition Inst., Prague), R. Rat, Z. Slabokhova and L. Blagnikova. Vop. Pitan. 25(5):3-7, 1966.

A total of 60 obese women (17-57 yr. old) who weighed from 160.6-288.2 pounds (20-120% overwt.) were studied. No specific symptoms of liver insufficiency were evident before wt. reduction. There was a change in liver function (mainly dye excretion) in approx. 50% of the women. The extent of disturbed liver dye excretion in obese women was dependent upon the degree of excessive wt., but was independent of the percentage of fat in the body. The women were divided into 3 groups according to the type of reducing diet: 1) a reducing diet of 1200 calories (including 80 g of protein); 2) an isocaloric reducing diet with high fat content (60-80% of caloricity) an low protein content (30-60 g); and 3) a simple reducing diet with thyreoglobulin-forte (given three times per day). Dye excretion improved i all three groups, but the changes were lowest i the third group. Liver dye excretion improved i parallel with wt. reduction. The authors emphasize that methodical errors can be made in determination of BSP retention and clearance in obese patients.

7371 SERUM ACTIVITY OF ENZYMES OF MITOCHONDRIAL INTRACELLULAR ORIGIN AND OF THOSE ORIGINATING IN SOLUBLE FRACTIONS OF CYTOPLASM, IN NORMAL SUBJECTS AND IN PATIENTS WITH LIVER DISEASES. (It.) Notarbartolo, A. (U. Palermo, Italy), F. Giglio, S. Le Moli, G. Migneco, P. Citarrella and L. Pagliaro. Fegato 12(3):332-340, 1966.

The mean percentages by which 6 serum enzyme activities were increased among 70 cirrhotic patients as compared to 35 normal subjects were tabulated as follows: ornithine-carbamyl transferase = 172%, glutamic dehydrogenase = 900%, SGOT$_2$ = 107.52%, SGOT$_1$ = 101.32%, succinic dehydrogenase = 200%, SGPT = 31.63%. Comparabl tabulations for 60 patients with hepatitis (av. of repeated determinations throughout the entir course of the disorder) were: 362.66%, 2022.50 316.70%, 979.01%, 6008.00% and 608.56%, resp. For 20 other patients with hepatitis (av. of repeated determinations during the first 14 day of jaundice, only), they were: 697.33%, 3350.0 652.32%, 2891.38%, 14,600.00% and 2363.33%, res Comparable tabulations for the mean percentage increase among cirrhotic patients as compared t that among the first group of hepatitis patient (above) were 47.42%, 44.49%, 33.95%, 10.34%, 3.32% and 5.19%, resp.; as compared to that amo the second group of hepatitis patients, they were 24.66%, 26.86%, 16.48%, 3.50%, 1.36% and 1.24%, resp. It is concluded that patients with acute hepatitis show a relatively greater increase of serum enzymes originating in the cell sap; cirrhotics, a relatively greater increase of those originating in the mitochondria. It is also concluded that, in the presence of an equal degree of cell damage, the mitochondria of the cirrhotic patient's liver cells release a relatively greater amount of serum-soluble enzymes than do those of the patient with acute hepatitis.

7372 QUANTITATIVE RADIOISOTOPIC APPROACHES TO HEPATIC SIZE AND FUNCTION. (E.) Spencer, R. P. (Yale U. Sch. Med., New Haven, Conn.). Amer. J. Dig. Dis. 12(5):515-522, 1967.

Mathematical aspects of radioisotope evaluation of liver structure and function are discussed. Hepatic size and wt. can be estimated from the scan and other means, and can be compared with wt. predicted by the equation: $A = T + E$, where A is the admin. activity, T the activity

specific tissue, E background body radio-
ivity. The degree of homogeneity of uptake
be measured by computer processing. The
outer can be used to correct for use of short-
ed radioisotopes (with minimal doses, studies
be able to be extended to children and
gnant women); simultaneous use of 2 radio-
topes to examine both parenchymal-cell and
iculoendothelial function; rapid entry into,
discharge from the liver.

3 VASCULAR PATTERN OF THE BILHARZIAL
LIVER AS DEMONSTRATED BY CAST TECHNIC.
) Farag, A. M. (Fac. Med., Alexandria,
ted Arab Republic) and M. Ghanem. Alexandria
. J. 12(2-3):73-86, 1966.

the 22 livers studied by corrosion casts, 5
e normal, 12 had schistosomiasis, 4 had
nnec's cirrhosis, and 1 had post-hepatic
rhosis. The portal vein was inj. with
olored palatal P4 resin, the hepatic artery
n red-colored resin, the hepatic vein (by
erior vena cava) with blue resin. The inj.
er was left for 8 days in 5% formalin, and
er tissue was removed by maceration in conc.
for 1 wk. In schistosomal hepatic fibrosis
uction of minute fourth order branches of the
tal tree was observed. There was no change
the caliber, pattern of division, and
tribution of the trunks and first-third order
nches, nor was there amputation, lacunae, or
tortion of the portal venous system as was
erved in Laennec's cirrhosis. A newly formed
cular network around the main portal tributar-
is characteristic of hepatic schistosomiasis.
hepatic artery was normal and did not show
irregularities present in Laennec's cirrhosis.
the hepatic venous system also was normal
gests that there is no increased resistance
hepatic blood outflow in this condition.

4 THE TERMINAL DISTRIBUTION OF THE
HEPATIC ARTERY AND ITS RELATIONSHIP TO
DEVELOPMENT OF FOCAL LIVER NECROSIS FOLLOW-
INTERRUPTION OF THE PORTAL BLOOD SUPPLY.
) Nakata, K. (Osaka Med. Coll., Japan) and
Kanbe. Acta Path. Jap. 16(3):313-321, 1966.

minal distribution of the hepatic artery of
human liver was studied by arterial inj. of
ia ink and serial sectioning. The control was
ealthy 24-yr.-old male accident victim, while
erruption of portal supply to the liver lobule
observed in a 53-yr.-old male victim of
mach cancer, a 37-yr.-old female who died
n toxemia of pregnancy and a 36-yr.-old male
died from widespread hepatic necrosis caused
ccidental surgical ligation of the common
atic artery, portal vein, and common bile
outside the liver. Branches of the hepatic
ery from capillary networks around the bile
in the portal tract, from which the
illaries (terminal venous branch) arise and
connect with sinusoids at the most peripheral zone of the liver lobules. Direct anastomosis of portal vein and hepatic artery was not observed. Studies on interruption of portal blood supply showed that the portal tract, its components, and several layers of parenchymal tissue around the portal tract are nourished by the peribiliary capillary plexus. It thus is unaffected by portal obstruction, while other parts of the liver lobule undergo coagulation necrosis. It is concluded that the 2 main functions of the hepatic artery are nourishment of the portal tract, especially the bile duct, and, to a lesser extent, the most peripheral layers of the liver lobules adjacent to the portal areas.

7375 PATHOGENESIS OF SO-CALLED INTRAHEPATIC CHOLESTASIS BASED ON THREE-DIMENSIONAL ANALYSIS OF THE CHOLANGIOLAR SYSTEM. (E.)
Takahashi, T. (Tohoku U. Sch. Med., Sendai, Japan) and T. Hayama. Tohoku J. Exp. Med. 91(2): 149-176, 1967.

Livers studied in 3-dimensional reconstruction of the cholangiolar system included 3 with intrahepatic cholestasis, 2 with subacute serum hepatitis, and 1 normal. Specimens were fixed in formalin, embedded in celloidin-paraffin, and 200-300 6 μ serial sections were made. In intrahepatic cholestasis, reconstruction analysis showed a disturbance in continuity of biliary pathways, not observed by routine histological examination. Regeneration of bile ductules is thought to follow formation of random indiscriminate cholangiolar lesions, but is not able to restore sufficient passage of bile flow. Both cases of serum hepatitis showed a similar cholangiolar derangement, suggesting that cholestasis accompanied viral hepatitis and this was exaggerated in intrahepatic cholestasis. When cholangiolar derangement persisted beyond recovery of liver cell injury, intrahepatic cholestasis (characterized by obstructive jaundice and absence of other serious liver function damage), was regarded as a sequela of hepatitis, most frequently of viral origin. It is concluded that intrahepatic cholestasis is not a separate pathological entity, but is best described as "cholangiolar derangement syndrome."

7376 THE RELATIONSHIP OF HYPERCAPNIA TO THE PRODUCTION OF KERNICTERUS. (E.)
Lending, M. (New York Med. Coll., N. Y.), L. B. Slobody and J. Mestern. Develop. Med. Child. Neurol. 9(2):145-151, 1967.

A bilirubin infusion (40 mg/kg in 20-30 ml saline) was given to 29 normal mongrel puppies under 3 mo. of age anesthetized with pentobarbital sodium to decrease pain reflexes but not respirations. Controls (8, Group 2) received bilirubin infusion only. Experimental puppies (21, Group 1) received bilirubin (to induce hyperbilirubinemia) and intermittent periods of hypercapnia, induced by endotracheal admin. of an approx. 93:7 mixture (varied) of O_2:CO_2 for 30-45 min., to cause respiratory acidosis (as measured by arterial blood pH, CO_2 levels, and clinical appearance). The following were measured: cisternal fluid level; serum bilirubin level; cerebrospinal fluid/serum bilirubin conc. ratio; gross study of brain stem and nuclear masses. In Group 1 hyperbilirubinemia, hypercapnia, and serum bilirubin levels of at least 20 mg/100 ml were maintained for 48 hr. Respiratory acidosis (pH 6.69 in 1; 7.22 in 2), but not hypoxia, was observed. Of these 21, 13 (62%) showed definite gross focal areas of bilirubin staining of nuclear masses. Controls showed only mild diffuse staining of brain, and no gross focal staining of nuclear masses. Both groups developed essentially the same degree of hyperbilirubinemia. The av. content of cerebrospinal fluid bilirubin was twice as great in dogs with kernicterus as those without (0.137 in 1, 0.091 in 2). The cerebrospinal fluid/serum ratio was also about 2.5 times greater in those with changes of nuclear staining. It is suggested that hypercapnia accompanied by respiratory acidosis alters the permeability of the blood-cerebrospinal fluid barrier in young puppies. When associated with hyperbilirubinemia it is an important factor in the production of kernicterus.

7377 BACTERAEMIA IN ASSOCIATION WITH HEPATOCELLULAR AND HEPATOBILIARY DISEASE. (E.) Jones, E. A. (Roy. Free Hosp., London), N. Crowley and S. Sherlock. Postgrad. Med. J. 43(Suppl.):7-11, 1967.

A study was made of 40 patients with bacteremia (46 cases) associated with hepatobiliary disease, 27 with cirrhosis. Patients were divided into 2 groups: hepatocellular disease (29) included cirrhosis (25), chronic active hepatitis (4), hepatobiliary disease (11) included obstructive disease of biliary tract (9), hepatic cyst (1), and intrahepatic abscess (1). The mortality rate was 59% in the first group and 27% in the second, and was twice as high in males as in females. In 34%, bacteremia occurred in the last 7 days of life. Gram-positive organisms predominated in the first group, gram-negative in the second. The major means of entry of organisms was the respiratory and gastrointestinal tract in the first group, and the biliary tract in the second. In 6 patients, bacteremia followed some sort of surgical procedure. In cirrhotics with bacteremia, 18% never had temperatures higher than 37.2°C, 85% lacked rigors, 52% never had blood pressure below 100 mm Hg, and 64% never had a peripheral WBC above 10,000/mm^3. In hepatocellular patients, bacteremia caused or worsened hepatic precoma or coma. In the first group bacteremia was associated with the presence of severe liver cell failure, in the second group with cholangitis or surgery to relieve obstruction. Many of the patients studied were on antibiotics.

7378 PRESENCE OF BILE ACIDS IN JAUNDICED HUMAN URINE. (E.) Gregg, J. A. (Mayo Clin., Rochester, Minn.). Nature (London) 214(5083):29-31, 1967.

An attempt to establish the presence of cholic and chenodeoxycholic acid in the urine of a 45-yr.-old female patient, with biliary cirrhos secondary to postoperative obstructive jaundice by thin-layer and gas-liquid chromatography is described. About 10 mg of each acid was estimated by spectrophotometric analysis in a 24-hr. urine sample. It is suggested that thes values constitute only a semiquantitative determination.

7379 CLAMPING OF THE HEPATIC PEDICLE UNDER REGIONAL HYPOTHERMIA (EXPERIMENTAL STUDY). (Fr.) Pouyet, M., C. Bacques, P. Béra and G. Bousquet. Lyon Chir. 63(1):119-124, 196

Side-to-side portacaval anastomosis under local hypothermia (10-15 min.) of the liver and 30-60 min. of clamping of the hepatic pedicle was performed in 33 dogs, 25 of which were evaluable. The survival rates after 30, 45 and 60 min. of hepatic pedicle clamping (5,10 and 10 animals resp.) were 100%, 90% and 60%, resp. Tolerance of the circulatory system to hepatic clamping was good, but release of the clamp always produced circulatory collapse of various degrees, usually reversible. No histological changes were noted in postoperative biopsies, but SGOT and SGPT levels (in 17 dogs) rose significantly (av. 529 and 475 U, resp.) to peak levels 1 hr. after release of the clamp, and remained elevated for the next 15 days. Coagulation tim and prothrombin titers (studied in 13 animals) remained normal; fibrinolysis factors were not observed, because the animals were routinely treated with ε-aminocaproic acid. Hyperglycemi was noted for 1 hr. after release of the clamp. It is concluded that 45 min. is the max permissible duration of hepatic occlusion in th dog, and that it should be performed clinically only when essential, because of its functional effects on the liver.

7380 A METHOD FOR VITAL MICROSCOPY OF THE HEPATIC MICROCIRCULATION IN LARGE ANIMALS AND MAN. (E.) Woodward, N. W., Jr. (Cook County Hosp., Chicago, Ill.), R. M. Vanecko and W. C. Shoemaker. J. Surg. Res. 7(4):173-176, 1967.

Continuous transillumination and photographic documentation of hepatic microcirculation in th Rhesus monkey using a modified Leitz Ultropak incident light illuminator is reported. Reflected light from a standard external source permitted continuous observation while a quartz electronic light (high intensity for 0.001 sec. placed in the light path enabled photographic documentation at magnifications of 22-176 power Photomicroscopy was accomplished by use of a

mm camera with both a split-beam adapter and
h speed film. Best color contrast of liver
sue was obtained by employment of a light
en transmission filter. Use of this technic
l obviate introduction of artifacts
ociated with manipulation and preparation of
specimen. This method has been used with
cess for over 2 yr. in studying hepatic
culation in shock and is applicable for study
other large parenchymal organs in large
mals and perhaps liver microcirculation in
.

FUNCTIONAL CONDITION OF THE LIVER IN PATIENTS WITH UTERINE BODY CANCER.

s.) Danova, L. A. (Inst. Oncology, Ministry
lic Health, Leningrad, USSR). Vop. Onkol.
9):43-48, 1966.

isturbance of the carbohydrate, pigment,
tein and detoxification functions of the
er was found in 80 patients with cancer of
body of the uterus. There was a decrease in
tolerance to glucose after loading in 30 of
patients tested; 22 had an increased hyper-
cemic coefficient (up to 2.5 or more) and in
the time of max. increase of blood sugar was
longed (from less than 60 to 150 min.). The
al bilirubin content was elevated in 10 of
and direct bilirubin was increased (more than
7 mg%) in 23 of 32 patients tested; there-
e, 32 of 54 had pathological changes of the
ices of pigment metabolism. Albumins were
eased in 21 of 52, and the globulin fraction
increased in 16 of 52 patients studied. The
umin-globulin coefficient was less than 1.3
24 of 52 patients. The Hg_2Cl_2 test was
ormal in 13. The excretion of hippuric acid
abnormal in 13. A disturbed detoxification
elimination of sodium benzoate was found in
of 39. Glutamine-asparagine transaminase
vity was somewhat above normal (from 40-85 U)
51% of the patients examined, and aldolase
normal in 15 patients. Based upon these
ical and laboratory data, the disturbance of
er function in patients with cancer of the
rine body corresponds to that found in
onic hepatitis.

DETECTION OF HEPATIC SHUNTS BY THE USE OF ^{131}I-MACROAGGREGATED ALBUMIN. (E.)

, H. (U. Tokyo), K. Kitani, H. Kameda, H.
ada and M. Iio. Gastroenterology 52(3):
-487, 1967.

jects were 23 patients (18 men, 5 women;
58 yr.) with hemolytic anemia (3), acute or
onic hepatitis (4), liver fibrosis and
enomegaly (1), hepatic cirrhosis (15).
gnosis was by functional tests, laparoscopy,
er biopsy, laparotomy examination, autopsy.
er scintigrams (25) were obtained immediately
er inj. of ^{131}I-macroaggregated albumin
μc/ml) into the spleen. A portal system
nt was diagnosed when the lung contour in
scintigrams was delineated, and the "shunt index" was calculated: = 100 X (total lung counts)/ (total liver counts) + (total lung counts). Prior to scanning, liver and lung accumulation curves were recorded in 13 patients by the above technic. One scintillation detector was placed over the right lobe of the liver, the second over the left upper lung field (slightly slanted toward the head to avoid scattered radioactivity from liver and spleen). From these, portal circulation time (spleen to liver; spleen to lung) was measured and intrahepatic shunts were searched for (presence indicated by initial hump in liver curve). Three with hemolytic anemia, 4 with hepatitis, and 2 with cirrhosis had no shunts. Collateral circulation in the splenoportal system was detected in 13 of 15 cirrhotics and 1 with liver fibrosis. Shunt indices were 18-90 in cirrhotics with shunts, and below 6 in patients without shunts. An initial hump in accumulation curves was observed in 7 cirrhotics, suggesting the presence of intrahepatic shunts. Spleen-to-liver circulation time was almost the same (approx. 2 min.) whether or not cirrhosis was present. Spleen-to-lung time through collateral veins ranged widely (5-12 min. with shunt only). Use of this radiocompound is an easy method for detection and semiquantitation of intra- and extrahepatic shunts in hepatic cirrhosis.

7383 MORPHOLOGICAL AND BIOCHEMICAL STUDIES OF BENIGN RECURRENT CHOLESTASIS. (E.)

Biempica, L. (Albert Einstein Coll. Med., Bronx, N. Y.), S. Gutstein and I. M. Arias. Gastroenterology 52(3):521-535, 1967.

A 27-yr.-old man had experienced 14 episodes of jaundice, pruritis, bilirubinemia and wt. loss since puberty. Onset was not associated with diet, alcohol, infection, sedatives or excessive physical activity, and remission was spontaneous in each episode. Icteric liver was diagnosed at 15 yr., with a normal extrahepatic biliary system. Diabetes mellitus was diagnosed at 25 and was well-controlled with tolbutamide. During episodes, bilirubin, alkaline phosphatase, and serum di- and trihydroxy bile acid conc. were increased, and tubular max. BSP and hepatic BSP storage were reduced. Simultaneous biopsy showed markedly altered canaliculi, with distorted and reduced microvilli; almost complete disappearance of nucleoside phosphatase activity; reduction in the number of acid phosphate-rich lysosomes. Intracellular bile pigment was common. Glycogen nuclei and lipid spheres were abundant and canalicular. In a second biopsy 10 mo. later during clinical remission, functional, cytochemical and ultrastructural studies showed a return to normal patterns with the exceptions of the presence of small amounts of intracellular and intracanalicular bile pigment; some glycogen-rich nuclei; presence of crystalline nucleoids within the microbodies.

7384 DECOMPRESSION OF PORTAL CIRCULATION BY GRAFTS OF PEDUNCULATED LUNG INTRODUCED INTO THE PARENCHYMA OF THE SPLEEN. (It.)

Rapisarda, L. M. (U. Palermo, Italy) and G. Barbera. Minerva Chir. 22(3):109-114, 1967.

In one group of dogs, progressive stenosis of the portal vein was induced by inserting cellophane at the level of the transverse fissure of the liver, creating a progressive portal hypertension which stabilized at 85 cm H_2O. In a second group, 2 decorticated, pleura-free strips of pulmonary parenchyma, each approx. 10 cm long and 6 mm thick, were grafted into a sort of tunnel of splenic parenchymal tissue after the spleen had been drawn up and fixed on the diaphragm. This was done at the same time the source of portal stenosis was created. In this second group of animals, portal hypertension developed at approx. the same rate, but stabilized at only 50 cm H_2O. Autopsy confirmed the creation of innumerable vascular and fibrous connections between the spleen and the pulmonary hilus and between the spleen, the diaphragm and the lung, consisting of neoformations and creating a considerable network which connected the portal and systemic circulations. Inj. of contrast material further confirmed the movement of liquid from the spleen, through the network in question, into the systemic circulation.

7385 RECURRENT JAUNDICE IN PREGNANCY. I. A CLINICAL AND ULTRASTRUCTURAL STUDY.

(E.) Adlercreutz, H. (U. Helsinki Meilahti Hosp.), A. Svanborg and Å. Ånberg. Amer. J. Med. 42(3):335-340, 1967.

A study of clinical symptoms, functional liver tests, and ultrastructural alterations in the liver was made in 10 patients (19-34 yr.): 7 pregnant for the first time; 1 pregnant and jaundiced for the second time; 2 pregnant and jaundiced for the third time. Clinical tests included: serum bilirubin, serum alkaline phosphatase, thymol turbidity, plasma proconvertin-prothrombin, SGOT, SGPT. Liver biopsies were performed at least once in each and were examined by light and electron microscopy. In 1 patient (36 yr. old) with pronounced and prolonged jaundice, surgical laparotomy revealed signs of intrahepatic cholecystatic jaundice. The amount of bile secreted (250-575 ml daily), secretion pressure, and bile viscosity (1.07-1.27) were normal. Jaundice disappeared within 2-3 wk. of spontaneous delivery, but a slight increase in SGOT, SGPT and serum alkaline phosphatase was observed for an additional 2 mo. Liver biopsy after 3 mo. was normal. Ultrastructural abnormalities were observed in all specimens during the period of jaundice, and these disappeared after delivery. Abnormalities included: dilatation of most bile canaliculi; regional disappearance of microvilli; some enlarged, elongated irregular mitochondria in the parenchymal liver cells. In sections of these giant mitochondria, inner membranes were replaced by systems of alternate dark and light parallel lamellae. These ultrastructural alterations of recurrent jaundice of pregnancy are thought to be nonspecific, since they have been observed in extrahepatic bile stasis and in infectious or toxic liver disease.

7386 IMMUNOFLUORESCENCE STUDY OF RHEUMATOID FACTOR IN LIVER TISSUE OF PATIENTS WITH RHEUMATOID ARTHRITIS AND HEPATIC DISEASES. (E.)

Bonomo, L. (U. Bari Med. Sch., Italy), A. Tursi and V. Minerva. J. Path. Bact. 92(2):423-431, 1966.

Fluorescent aggregated human γ-globulin was used to demonstrate rheumatoid factor in liver biopsy sections from 20 patients, all seropositive for rheumatoid factor, who had rheumatoid arthritis, systemic sclerosis, hepatic diseases (mainly active viral hepatitis and postnecrotic cirrhosis) and other diseases. The macroglobuli character of the globulin reactive with fluorescent aggregated γ-globulin was confirmed by staining with fluorescent anti-19S γ-globulin antiserum and treatment of liver sections with 2-mercaptoethanol. Both rheumatoid factor-seropositive and -seronegative patients had γ-globulin-containing cells, but these were much more numerous in the seropositive biopsies. Cellular rheumatoid factor could not be demonstrated in 29 liver specimens taken from control patients, all seronegative, with various disease conditions. The rheumatoid factor-containing cells had the appearance of reticulo-endothelial Kupffer or plasma cells. The number of rheumatoid factor-containing cells in the liver disease group was often equal to or greater than that in rheumatoid arthritis, despite the higher serum rheumatoid factor levels in the rheumatoid arthritis group.

7387 ADENOSINE DEAMINASE ACTIVITY IN LIVER DISEASES. (E.)

Secchi, G. C. (U. Milan, Italy), A. Rezzonico and N. Gervasini. Enzym. Biol. Clin. (Basel) 8(1):67-72, 1967.

Levels of adenosine deaminase activity were measured in normals (13) and subjects with early liver cirrhosis (7), advanced cirrhosis (27), hepatic coma (6) and viral hepatitis (16). Diagnosis was confirmed by needle biopsy and liver function tests. Patients with early hepatic cirrhosis (23 I.U.) and those with viral hepatitis showed a marked, significant increase in serum adenosine deaminase activity. Levels were slightly elevated with advanced cirrhosis (11 I.U.), but not at all with hepatic coma (4 I.U.). Normals ranged from 3-6 I.U. The progressive decrease in enzyme activity with advanced cirrhosis and hepatic coma was statistically significant in comparison with early cirrhosis. Increased levels may be related to cell necrosis or damage during the e of cirrhosis. Decreased levels may be o the failure of protein synthesis in the , which becomes more evident in terminal osis and coma, when the cell's synthetic atus is injured, causing a fall in cell and a enzyme conc. There was no correlation en changes in this enzyme and those in serum proteins synthesized in the liver as prothrombin, cholinesterase, α_2-globulins lbumin, but there was a significant lation between decrease in enzyme activity ncrease in blood ammonia. It is concluded in advanced cirrhosis and hepatic coma, evels may be caused by a reduction in ic synthesis of the enzyme, incomplete esis of enzyme, metabolic readjustment or olite repression.

CAPNOSPLENOPORTOGRAPHY. ASSESSMENT OF PORTAL VEIN PATENCY IN DOGS WITH CAR-IOXIDE GAS. (E.) Hipona, F. A. (Harvard Sch., Boston, Mass.) and W. M. Park. Amer. entgen. 99(3):606-611, 1967.

splenoportography, the use of CO_2 gas as a negative contrast material in splenography under experimental conditions, was to study the portal venous system in dogs e normal, after partial and complete sion of the portal vein and in simulated l hypertension. Comparative serial genograms were done using 60% methylglucamine izoate (1 ml/kg) and CO_2 gas (2-3 ml/kg, ml/kg). Partial or complete occlusions e portal vein either directly or by teral vessels was shown with capnooportography, whereas similar results were onsistently reproduced with conventional ive contrast agents when blood flow was ly hepatofugal. Patency of the portal vein nown very well with capnosplenoportography tificially-induced portal venous hyperon; with 60% methylglucamine diatrizoate, was poor visualization of the portal vein se of dilution of the contrast material, ming (a mixing defect) had prolonged transit in the portal vein. A left posterior ue projection is considered to be the ideal ion for this technic; in the normal, ion of examination is 10 sec., with optimal stration of the portal vein occurring 2-4 after the start of inj. This does not e appreciably, even under conditions of ed experimental pathology. A dose of 2-3 of CO_2 gas is considered adequate for good lization of the splenoportal venous system. echnic is clinically applicable in patients re hypersensitive to iodinated contrast and in cases where there is nonvisualizaof the portal vein by conventional splenoraphy.

STUDIES ON AZIDE, CAERULOPLASMIN AND COPPER IN RELATION TO WILSON'S DISEASE Williams, A. O. (U. Ibadan, Nigeria). J. Exp. Path. 48(2):180-187, 1967.

Male Wistar rats were divided into 5 groups: Group 1, 6 normal rats given 0.02% sodium azide soln. as a substitute for drinking H_2O for 120 days; Group 2, 6 normal rats given 0.2% copper acetate soln. as a substitute for drinking H_2O for 320 days; Group 3, 6 rats given 0.2% copper acetate soln. for 200 days and then 0.02% sodium azide soln. for 120 days instead of drinking H_2O; Group 4, 6 rats given 0.2% copper acetate soln. for 200 days and then a mixture of 0.02% sodium azide in 0.2% copper acetate soln. instead of drinking H_2O for 120 days; and Group 5, 12 control rats given ordinary drinking water. The minimum lethal conc. 50 (MLC_{50}) for sodium azide was 0.05% and for copper acetate, 0.5%. Serum copper oxidase was assessed as an indication of ceruloplasmin, and SGPT as a test of liver function. There was no mortality in any of the groups of rats and no significant differences in av. wt. of the animals. In all the livers of rats given sodium azide for 120 days, the only significant histological change was focal liver cell necrosis with mononuclear cellular reaction; portal tracts showed no significant lesion and the reticulin framework was intact, except in areas of focal necrosis. Similar histological changes were noted in livers of rats given copper acetate for 320 days, and also in rats with a combination of copper acetate and sodium azide intake. Rats in Groups 3 and 4 had the highest av. Cu content in the liver (40.75 and 46.76 µg/g of wet tissue, resp.); in the presence of increased tissue Cu in these rats, there was a significant reduction in the level of serum ceruloplasmin attributable to ingestion of the sodium azide soln. Capacity of the liver to synthesize or produce albumin was impaired in Group 1 and 2 rats, as reflected on electrophoretic analyses of serum proteins; the diminution in the albumin fraction was consistent with hepato-cellular damage due to either Cu or azide. There was only a slight reduction of the albumin fraction in the sera of Group 3 and 4 rats. Estimations of SGPT in the various groups showed a variable but gradual increase of enzyme conc. in all rats, but the overall increase of SGPT was not as high in Group 3 and 4 rats with a combination of Cu and azide when compared with the other groups of rats. It is concluded that sodium azide is hepatotoxic and produces histopathological changes similar to chronic Cu poisoning, and that it produces a transient fall in the serum ceruloplasmin level in Cu-poisoned, but not in normal, rats. It is unlikely that diminished ceruloplasmin alone plays any significant role in the pathogenesis of hepatic lesions. The cerebral pathology produced by these various sodium azide and Cu parameters is also analyzed and discussed.

7390 HEMOLYTIC ANEMIA IN WILSON'S DISEASE. (E.) McIntyre, N. (Roy. Free Hosp., London), H. M. Clink, A. J. Levi, J. N. Cumings and S. Sherlock. New Eng. J. Med. 276(8): 439-444, 1967.

Three patients (9 and 12-yr.-old boys, and a 21-yr.-old woman) with hepatolenticular degeneration and associated acute hemolytic episodes are described. During attacks of hemolysis large amounts of Cu were excreted in the urine. Clinical and laboratory evidence of liver disease were present, and cirrhosis was proven histologically. Kayser-Fleischer rings were noted, and 1 case also presented mild neurologic features. In 2 cases serum ceruloplasmin was low; in all 3 urinary Cu output (1300-6590 μg) was well above normal. Postmortem analysis of 2 cases revealed a high Cu content of the liver (162 mg/100 g dry tissue in 1 case), which was strongly suggestive of hepatolenticular degeneration. Moderate or severe anemia of sudden onset was associated with reticulocytosis and with the appearance or exacerbation of jaundice; the 2 younger patients had normoblastic hyperplasia of the bone marrow. The ^{51}Cr half-life of RBC was markedly reduced. In 2 cases there was no significant loss of blood into the intestine; in the third, fecal loss was inadequate to account for the short RBC half-life. The 12-yr.-old boy had repeated episodes of hemolysis, with transient but definite periods of improvement for 8 mo. before death from hemorrhage due to esophageal varices. The 9-yr.-old boy died 1 mo. after the first attack of hemolysis. In the 21-yr.-old woman, a hemolytic reaction developed 12 yr. after appearance of signs of hepatolenticular degeneration. In the 2 young boys, the hemolytic episode was initially confused with hepatocellular failure, and in all 3 ascites developed at this time, adding to difficulties in diagnosis. The mechanism of production of hemolysis is discussed. The sudden release of Cu from tissues into blood, with resultant hemolysis of RBC, is a mechanism analogous to that of enzootic jaundice in sheep and is regarded as the most likely explanation of the acute hemolytic episodes.

7391 A NEW METHOD FOR TOTAL, FREE, AND CONJUGATED SERUM BILIRUBIN. (E.)

Ferro, P. V. (Dade Reagents, Inc., Miami, Fla.) and A. B. Ham. Amer. J. Clin. Path. 47(4): 472-480, 1967.

A new method for quantitative determination of total, free and conjugated serum bilirubin is described. The proposed method estimates total and free bilirubin, and the conjugated fraction is expressed as the difference of these 2 values. An alternate approach determines free and conjugated bilirubin, and total bilirubin is expressed as the sum of these 2 fractions. For total bilirubin, the proposed method requires that serum be added to a mixture of chloroform and a stable oxidizing agent. The mixture is incubated for 10 min. at 37°C or 5 min. at 56°C, and the stable blue color is read at 640-660 mμ. For free and conjugated bilirubin, serum is added to the acidified solvent and chloroform is added; the mixture is shaken for 20-30 sec. and centrifuged. Aliquots of the chloroform layer containing the free bilirubin and the upper layer containing the conjugated bilirubin are removed and subjected to the same oxidation technic as that used for total bilirubin. Determinations using this method were made on sera from 68 supposedly normal donors. The range for total bilirubin was found to be 0.2-0.9 mg/100 ml, with an av. of 0.5 mg; for free bilirubin, the range was 0.2-0.8 mg/100 ml with an av. of 0.4 mg, and the conjugated bilirubin range was 0-0.2 mg/100 ml, with an av. of 0.07 mg. The new method had excellent reproducability. A comparison of the Malloy-Evelyn method (Klatskin and Drill 1-min. direct procedure) with the author's method on 20 norma sera showed no significant difference in the values obtained for total bilirubin and the 2 bilirubin fractions. With abnormal sera the 2 methods varied greatly in values for the 2 bilirubin fractions. In the author's method, values for free bilirubin were one-third those of the indirect values obtained with the Malloy-Evelyn method. The author's method also showed an increase of approx. 50% in the amount of conjugated bilirubin, compared with the direct determination by the Malloy-Evelyn procedure. Sera with total bilirubins as high as 65 mg/100 ml were tested. With the test ser used, no serum of nonhemolytic origin showed a free bilirubin value in excess of 8 mg/100 ml. The highest indirect bilirubin value by the Malloy-Evelyn method was 25.5 mg.

7392 AN ASSOCIATION OF HEMOCHROMATOSIS AND HYPERLIPEMIA. DEMONSTRATION OF THE GENETIC TRANSMISSION OF THESE TWO CONDITIONS.

(Fr.) Luton, J. P. (Med. Soc. Hosp., Paris), J. L. De Gennes and P. Rambert. Bull. Soc. Med Hop. Paris 117(12):1197-1210, 1966.

A unique case involving a 36-yr.-old male prese the possibility of the coexistence of familial hemochromatosis and familial hyperlipemia. Extensive studies were conducted to demonstrate that the hyperlipemia was not a secondary symptom of the hemochromatosis. For example, the hyperlipemia remained at high levels after the acid ketosis was totally corrected and the hyperglycemia of the diabetes was partially corrected; no pancreatic dysfunction was detected which could explain the lipid anomalie and hepatic function appeared normal which eliminated the possibility of a default in the purification of the chylomicra originating from the alimentary tract. It is concluded that thi was a case of endogenous hyperlipemia of geneti origin. The condition is evident in several family members; both a grandparent and uncle were diabetic. In this case, the diabetes was insulin-dependent, requiring 108 U of insulin per day. The hemochromatosis present also seemed to be a primary rather than secondary condition as it occurred at the age of 20 yr.

to any history of diabetes, fatty liver or
anomalies. It also seems genetically
mitted as the patient's mother had the same
culty.

THE MECHANISM OF ACTION OF CORTICO-
STEROIDS ON THE BILIARY SYNDROME IN
IC HEPATITIS AND CIRRHOSIS. (Fr.) Fodor,
rd Med. Clin., Cluj, Rumania), F. Barbarino,
coara and I. Fratila. Rev. Int. Hepat.
:1327-1343, 1966.

ications in the biliary syndrome noted in
tients with postviral chronic hepatitis were
ced by the admin. of 4 mg/day for 5 days of
-fluoro-delta-hydrocortisone. The follow-
hanges in the economization of bilirubin
recorded: a decrease in the bilirubinemia
an av. of 1.28 mg% to an av. of 0.69 mg%;
onc. of bile pigments in the hepatic bile
ased from an av. of 5.75 mg% to 7.84 mg%;
he rate of conjugated bilirubin/nonconjugated
ubin increased in the bile. Measurements
with BSP following the admin. of the
costeroid showed a decrease in the serous
tion of BSP, an improvement in the urinary
nation of BSP, a reduction in the time
en the admin. and the appearance of BSP in
le, and an increase in the biliary conc.
as well as the conjugated fraction. In
on, transaminase studies showed a decrease
level of serum transaminase (attributed
orrection in membrane permeability). The
f albuminemia increased while the gamma
ins remained the same. Values of the
reaction were reduced. From these data
concluded that the cortisone induced the
ion of hepatocellular enzymes which play a
n conjugation and protein-synthesizing
on.

SOME CLINICAL AND EXPERIMENTAL
OBSERVATIONS ON SERUM PEPTIDASE
TY IN HEPATIC DISORDERS. (E.) Horký, J.
Human Nutr., Prague), Z. Placer and O.
. Clin. Chim. Acta 16(2):279-285, 1967.

peptidase activity, as measured by the
metric method, in humans and rats
imental models) with different liver
es, is compared with the anatomical
ion and liver function tests. Clinical
ts (60) suffered from acute hepatitis (5),
c hepatitis (8), cirrhosis (24), cholestatic
ce (7), other liver diseases (9) and post-
c syndromes without a detectable liver
(7). Highest activity was found in
tatic jaundice and acute conditions. On
sis of anatomical comparison, highest
were obtained in cholestasis and necrosis
er cells. Compared with functional tests,
ty correlated most closely with bili-
mia and alkaline phosphatase, and quite
y with cholesterol and serum albumins. In
stic disease, patients with hepatic and
extrahepatic metastases had the highest levels. In experimental necrosis, liver peptidase activity fell and serum rose. In experimental cholestasis, serum peptidase activity, and later liver, rose. During the first days of liver regeneration, both levels rose but soon returned to normal. In experimental cirrhosis, liver activity remained the same, while serum rose. It is concluded that a high serum peptidase is not specific for hepatic disease.

7395 THE RELATIONSHIP BETWEEN HEPATIC GLUTATHIONE CONJUGATION AND BSP EXCRETION AND THE EFFECT OF THERAPEUTIC AGENTS. (E.) Boyland, E. (Roy. Cancer Hosp., London) and P. L. Grover. Clin. Chim. Acta 16(2): 205-213, 1967.

Rat and human liver biopsy specimens obtained at laparotomy were used. There are 3 stages in plasma clearance of circulating BSP: hepatic uptake and intrahepatic conjugation of dye followed by biliary secretion of free and conjugated dye. Overall rate of dye clearance is limited by the slowest step. In 5 patients with hepatic cirrhosis there was a marked decrease in activity of glutathione S-aryltransferase (enzyme responsible for hepatic conjugation of BSP with glutathione) compared with 3 normal livers, but only 3 of 5 showed a corresponding increase in dye retention. These results suggest that a slight increase in dye retention may be accompanied by a much more marked fall in enzyme activity. Low enzyme activity coupled with normal dye retention provides strong evidence that the activity of conjugating enzyme is not rate-limiting in normal liver. In *in vitro* studies, compounds causing jaundice and dye retention were examined as potential inhibitors of conjugating enzyme. Inhibition was by benziodarone (100%), flavaspidic acid (94%), iodopanoic acid (80.5%), bunamiodyl (64.5%), biligrafin (50.5%), novobiocin (47.1%), and others. It is suggested that enzyme inhibition by radio-opaque cholecystographic agents and male fern extract (flavaspidic acid) may be due to the presence of iodine atoms which are not activated by electron-withdrawing groups in the molecule and are therefore not replaced by glutathione at the active center. Benziodarone, a coronary dilator, was studied in rabbits and was found to reduce dye conjugation without affecting hepatic uptake or excretion.

7396 CHANGES IN ACTIVITY OF SERUM CHOLINESTERASE IN DIFFERENT LIVER DISEASES, ESPECIALLY IN INFECTIOUS HEPATITIS OF THE ADULT. (Ger.) Otto, H. (Region. Hosp., Kothen, Germany). Deutsch. Gesundh. 22(18): 841-846, 1967.

The author reviews the methods by which serum cholinesterase can be determined. For his own work he used the "Acholtest paper" of the Linz Sulfur Co. and the Biophan C-paper. Normal values were from 4 min. (high activity) to 18 min. (low activity) with an av. of 12.7 min. marked by a change to green. Translated into U, 20 U would correspond to 4 min. and 5.6 U to 18 min. In another list 20 normal people had activities expressed in min. from 4-10; 86 new cases of hepatitis, 4-16 min.; severe cases, 25 min.; 74 cases hepatitis of 2 and 3 wk., 4-10 min.; severe cases, 25 min.; 60 cases of hepatitis, 4-6 wk., 5-28 min.; 46 cases of hepatitis after 6 wk., 28 min.; 5 jaundice of pregnancy, 14-25 min.; 1 cholangitis and diabetes, 5 min.; 1 hepatitis with mononucleosis, 10 min.; familial jaundice, 11 min.; 30 healthy men, 4-9 min. Although serum cholinesterase decreases as damage to liver parenchyma increases, the author's data show that 60% of the cases lie within the 10-min. value and almost all are within the 18-min. limit of his definition. The values of cholinesterase, as determined by the test paper method at least, overlap too freely between the normal individuals and those with liver disease for this test to be considered as a liver function test or even as an indication of a trend toward increased hepatic damage.

7397 OUR EXPERIENCES WITH THE OIB-TEST (A TEST OF LIVER FUNCTION FOLLOWING THE METABOLISM OF ^{131}I-ORTHOIODOBENZOIC ACID. (Ger.)

Dohnálek, J. (Purkyne U., Brno, Czechoslovakia), M. Eysselt, K. Martínek and D. Kadlecová. Nuclearmedizin 6(1):76-86, 1967.

Normal controls (66) and 304 patients with hepatic or malignant diseases (45 with chronic hepatitis, 29 with liver cirrhosis, 55 with chronic cholecystitis, 25 having duodenal ulcer, 54 with mammary carcinoma, 52 with pulmonary carcinoma, 20 having laryngeal carcinoma and 24 suffering from malignant lymphogranuloma) were given 1 oral dose of 2 mg ^{131}I-labeled orthoiodobenzoic acid with 20 μc radioactive I_2; 4 metabolites of this compound were measured by scintillation counts after separation by electrophoresis from urine samples collected for uniform periods after the admin. of the oral dose. The metabolites were (1) o-iodobenzoyl-glucuronide, making up the largest amount, about 70% normally, (2) o-iodohippurate, normally about 6% of the total products, (3) o-iodobenzoate, normally about 22% and (4) the fourth fraction, in healthy subjects about 4-5%. The excretion rate, expressed as the time required for the excretion of half the oral dose or its products, was 7-9 hr. in healthy young subjects and 9-11 hr. in healthy older subjects. The excretion of each type of metabolite was established for the control group and for each group with a different pathology. Most useful was the percentage of each type of metabolite at the time of half-excretion, and of these the percentage of the first fraction was most revealing. Thus, in the control group this value was 67%; for patients with liver cirrhosis, 76.4%; chronic hepatitis, 74.2%; cholecystitis, 75.1%, duodenal ulcer, 67.1%; mammary carcinoma, 79.1%; lung carcino 83.1%; lymphogranuloma, 78.5%; and laryngeal carcinoma, 73.9%. Excretion of o-iodobenzoyl glucuronide was significantly elevated above the normal value in every pathological condit tested except duodenal ulcer; the values of t 3 other metabolic fractions excreted were als normal in duodenal ulcer. Considerable variation existed in the percentages of the 3 other metabolite categories in the different pathologies, but the number of patients was t small to establish definite trends.

7398 THE EFFECT OF EXPERIMENTAL HEPATIC CONGESTION ON THE ^{131}I ROSE BENGAL TEST, SERUM TRANSAMINASES AND THE HISTOLOGICA PICTURE PRESENTED BY THE LIVER. (Ger.)

Breining, H. (U. Erlangen-Nuremberg, Germany) O. Strubelt, H. Wust and B. Helpap. Z. Gastroent. 5(1):20-25, 1967.

Rats (180-350 g) were subjected to partial occlusion of the hepatic veins. During 2 int after operation, the animals underwent (1) th ^{131}I rose bengal test, (2) determination of and SGOT, (3) paper electrophoresis of serum establish protein levels, and (4) histologic examination of the liver; 11 rats were in Gr 1, tested between 4 and 5 wk. after operatio and 25 in Group 2, tested between 10-12 wk. after surgery. Liver excretion of rose beng in Group 1 and the controls was the same; Gr 2 animals, however, showed a decrease of 25% rate of dye excretion as compared to the controls. SGPT was increased from 35 (contr to 80.9 U/ml and SGOT from 76.5 (control) to 117.7 U/ml in Group 2. Transaminase levels Group 1 were not significantly increased. I neither group was there any significant chan in serum proteins; no decrease of albumin or increase of gamma globulin was observed. Histologically only very minor pathological changes were encountered in the experimental animals; occasional livers showed increased blood vol. in the central thickened veins an the sinusoids; in a single case collagen deposition was seen in the central acinar reticulum with fibrosis and activation of mesenchyma. Histologic differences between 2 groups were not evident. The observed cha of liver function probably arose from defici oxygenation of hepatic tissue. The rose ben and serum transaminase tests seem to be usef indicators of hepatic damage caused by defic blood flow.

7399 THE INTRAVENOUS GALACTOSE TOLERANCE AS AN INDEX OF LIVER FUNCTION. (Ge

Rommel, K. (U. Giessen, Germany), R. Böhmer W. E. Adam. Schweiz. Med. Wschr. 97(15):484 1967.

One group had normal, the other group diseas livers, proved by extensive clinical and

ratory findings, secured by biopsy in each
on. Galactose (0.125 g/kg body wt.) was inj.
in 2 min. into the fasting subject.
nning 10 min. after inj., blood samples were
n at 5-min. intervals and analyzed for
ctose. Under the same conditions in 4 nor-
subjects a tracer dose of 25 μc of radioactive
ctose was inj.; at various time intervals
een 3 and 20 and between 13 and 32 min.
d samples were obtained, the plasma taken up
ilter paper, ashed, and the radioactivity
rtained in a scintillation counter. The
lts were plotted on a half-logarithmic
; (the conc. of a substance decreases
nentially when it is being eliminated from
blood). The curves obtained with the radio-
ve galactose were different from those
ined by analysis of whole galactose in the
d, because radioactive breakdown products of
sugar remained in the blood yielding higher
es. The rate of galactose elimination from
d in subjects with damaged livers was one-
d less than in healthy subjects. The blood
l decreased about 6.2%/min. in those with
tic disease and about 10% in the normal.
differences were statistically significant
roup av. The wide individual ranges which
lapped between the 2 groups preclude the use
his test. Radioactive galactose should be
ul to demonstrate partition of the sugar in
etion, storage, and metabolism.

NONSPECIFIC ESTERASE ACTIVITY (TOTAL
AND FRACTIONATED) IN LIVER DISORDERS OF
DHOOD. (PRELIMINARY STUDY). (It.)
ascale, A. (Civil Hosp., Padua, Italy) and
stuni. Epatologia 12(3):481-487, 1966.

ats treated with P in oil soln., 1:1000, 5
0 ml, i.m., single dose, 24 hr. prior to
ifice, total serum esterase activity ranged
2800-3400 U in the presence of moderate
liver and from 1500-1800 U in the presence
evere fatty liver, as compared to a range of
-5180 U in intact controls. In rats admin.
i.m., 1 and 3 ml, single dose, 24 hr. before
ifice, it ranged from 2600-3400 U in the
ence of moderate necrosis and from 1400-2800
the presence of severe necrosis. Comparable
ations for fluoride-resistant serum esterase
ity were 940-1100 U, 810-960 U, 2400-3300
ontrols), 1040-1620 U and 720-940 U, resp.
ranges of total serum esterase and fluoride-
tant serum esterase activity were also
rmined for 30 normal adult human subjects,
ollows: 280-345 U and 30-46 U, resp. For
ealthy children, aged 3-12 yr., comparable
es were 480-585 U and 50-61 U, resp; for 45
dren with viral hepatitis, they were 320-520
69-106 U, resp.; for 18 children with
, noninfectious liver disorders, they were
20 U and 30-64 U, resp. It is concluded
the onset of viral hepatitis is accompanied
significant decrease of total serum
ase and a concomitant rise of fluoride-resistant serum esterase activity. In cases which recovered promptly, both values were normalized progressively; in cases which recovered only slowly, both values tended to remain abnormal for considerable periods of time, with decrease and increase, resp., directly in proportion to the extent of hepatocellular damage.

498 LIVER DAMAGE AND DEATH AFTER SURVIVAL OF SEVERE LIVING CONDITIONS. (Ger.) ietze, A. (Med. Service for Schleswig-Holstein, eumunster, Germany). Acta Hepatosplen. Stuttgart) 14(2):104-109, 1967.

he incidence of liver disease was investigated n a group of 308 soldiers, imprisoned, subseuently returned home, and deceased during the eriod of 1948-1964. These individuals had all een examined clinically and many by laparoscopy nd biopsy; all were autopsied after death; 63 ere known while living to have had liver disease; iver disorders were proved in 9 by postmortem xamination. All had lived for a long time under xtreme conditions of poor or deficient diet and ncreased risk of infection by hepatitis and limentary disorders. The incidence of liver isease in the general population, not living nder extreme conditions during the same period, as 3-6%. Among the former prisoners, 72 (23%) uffered severe liver disorders; liver disease as the direct cause of death in 46 cases (15%), nd was a strong contributing factor in the death f 26 (8%). The causes of death among the 72 ith severe liver disease were: Death directly ue to liver disease, 46 cases; 34 died in epatic coma; 10 from hemorrhage, esophageal, tc.; and 2 from primary hepatic carcinoma in irrhotic livers. The 26 deaths to which liver isease was a contributing factor were: 3 cases f carcinoma of the respiratory tract; 6 cases f other types of carcinoma; 7 deaths during bdominal surgery; 3 cases of cardiac infarct nd coronary sclerosis; 2 of heart failure and ndocarditis; 2 of pulmonary tuberculosis; 1 of hronic bronchitis; 1 of hypertension; and 1 of ccident.

499 THE LIVER AND CONSUMPTION OF BEER. (Ger.) Frank, H. (Sophia Hosp., ienna), W. Heil and I. Leodolter. Munchen. ed. Wschr. 109(16):892-897, 1967.

he connection between long term and excessive eer drinking and liver damage was investigated n 450 men, (1) 200 of them brewery workers, 2) 100 metal workers from a plant in the vicinity f the brewery, and (3) 150 other metal workers mployed at a distance from the brewery. Medical istories were taken with special reference to aundice, diabetes mellitus, and abdominal operaions to rule out other toxic conditions damaging o the liver. The workers' drinking habits ere established by personally questioning each ne. The subjects were thoroughly examined and he size of liver determined; they then underent an extensive battery of tests including iopsies. There was 80% agreement with respect o hepatic damage indicated by the BSP test and etermined by histology. In retrospect, the etermination of serum enzyme activities was f least value in the assessment of chronic damage o liver parenchyma. The 3 tests which showed the highest correlation in indicating the degree of liver damage caused by alcohol were: measurement of size of liver, BSP excretion test and histology. The authors state that the age distribution (20-65 yr.) was about the same in the 3 groups, but 99 (49.5%) of the brewery workers were between 51 and 65 yr. old, 45 (45%) of Group 2 were in this age bracket, but only 41 (27.3%) of Group 3. The daily consumption of alcohol in the form of beer established the categories of light drinkers (less than 80 g of alcohol or less than 4.5 liters of beer), medium drinkers (between 80 and 160 g of alcohol), and heavy drinkers (over 160 g of alcohol). Group 1 had 47 light (11), 113 medium (24), and 40 heavy (17) drinkers, with the incidence of liver damage in parentheses. The distribution in Group 2 was 68 light (10), 24 medium (7) and 8 heavy (7) drinkers. Group 3 had 90 light (3), 42 medium (5) and 18 heavy (6) drinkers. In Group 1 52 (26%) had damaged livers; in Group 2 22 (22%), and in Group 3 14 (9.3%). No case of malnutrition was observed among the 450 subjects. In the age bracket to 35 yr. liver damage occurred in 18% of Group 1, 16% of Group 2 and 4.5% of Group 3; in the span 36-50 yr. the percentages were, resp., 17, 22, and 6.1; and in the age group of 51-65 yr., the percentages were 33, 27, and 20. These are the percentages of the number of men of the particular group in the designated age category. The incidence of liver damage increased significantly with increased daily consumption of alcohol and with increasing age.

7500 LIVER CHANGES CAUSED BY ENDOTOXIN DURING PREGNANCY. (Ger.) Székesi, J. (Johannes Hosp., Budapest, Hungary). Zbl. Gynaek. 89(6):202-205, 1967.

Gravid white rats (16.5-18.5 days) were inj. i.p. with LD_{10} dose of endotoxin of Serratia marcescens. Animals were killed 1, 4, 24, and 48 hr. after inj. and the organs prepared for histologic examination. Of 16 gravid rats, 15 (94%) showed definite evidence of liver damage; damage to the kidney had occurred in 9 (56%), in the lungs in 6 (38), in the adrenals in 3 (19%) and in the spleen in 2 (13%). Endotoxin damage to all these organs has been adequately described except for the liver. One hr. after endotoxin inj. the liver showed definite hyperemia; 4 hr. after inj. numerous microthrombi appeared in the hepatic vessels in the first instance in the capillaries; the thrombi arose from aggregations of thrombocytes. The picture 24 and 48 hr. after inj. was one of destructive, continuing necrosis. The thromboses were accompanied by bleeding and necrosis, later surrounded and infiltrated by macrophages. By contrast the nongravid controls showed only hyperemia of the liver.

7501 LIVER DAMAGE CAUSED BY DIFFERENT TYPES OF ALCOHOLIC BEVERAGES. (Ger.)

Lelbach, W. K. (Med. Univ. Bonn, Germany). Deutsch. Med. Wschr. 92(6):233-238, 1967.

A survey was made among 525 institutionalized alcoholics as to the type of beverage consumed, the daily intake of alcohol in g and the duration of the drinking habit for correlation with the type and degree of liver damage assessed in these patients by the following tests: (1) BSP, (2) urobilinogen, (3) serum bilirubin, (4) SGPT and SGOT, (5) alkaline phosphatase, (6) cholinesterase, (7) thymol turbidity, (8) Takata, (9) total protein, and albumin and globulin determinations. Patients (75) were also biopsied. Only beer was consumed by 229 (49.3%), 27 (5.1%) drank beer in combination with other drinks of low alcoholic content, 44 (8.4%) were wine drinkers only or wine in combination with other low alcoholic beverages, 5 (1.0%) drank vermouth alone or with other low alcoholic beverages, and 190 (36.2%) consumed spirits alone or with other alcoholic drinks. Little or no statistical difference was found between beer and liquor drinkers with respect to liver damage; there was a close correlation between the amount of daily alcohol consumption and liver damage, and especially between the duration of the drinking habit and liver damage. The type of drink apparently has no effect upon the degree of liver damage. The 40 beer drinkers (B) and the 35 liquor drinkers (L) with liver biopsies had the following histologically-verified conditions: (a) 12% B, 17% L were histologically normal; (b) 30% B, 20% L had fatty infiltration of the parenchyma without inflammatory mesenchymal changes; (c) 15% B, 12% L had fatty infiltration with inflammation; (d) 10% B, 20% L chronic hepatitis with and without fatty infiltration; (e) 33% B, 31% L cirrhosis. These 2 groups were matched in the daily consumption of alcohol. It is apparent that the central factor in liver damage among alcoholics is the alcohol itself.

7502 LIVER DAMAGE IN CHRONIC ALCOHOLISM. (Ger.) Lelbach, W. K. (U. Bonn, Venusberg, Germany). Acta Hepatosplen. (Stuttgart) 94(1):9-39, 1967.

Liver biopsies were obtained from 320 alcoholics; the histological findings were correlated with age, duration of alcoholic abuse, and amount of alcohol consumed/day. These alcoholics were on withdrawal for an av. of 10-12 wk. In only 22% was no pathologic change observed; 38% had fatty liver; 40% showed more severe hepatic damage. Cirrhosis was present in 12%. The severity of histologic liver damage increased with the mean age of the case and with the duration of the alcoholism and the amount consumed per day. When the amount consumed exceeded 160 g/day the pathological changes in the liver were more pronounced than when the alcoholic consumption was less than 160 g/day; this difference was statistically significant as was the duration of alcoholic abuse; thus cirrhosis was found in every fourth alcoholic of 12-13 yr. duration; after 22 yr. cirrhosis was found in every secon individual. The incidence of lesions such as fatty liver complicated by inflammation increase steadily up to a mean alcohol abuse of 13 yr. Cirrhosis was mostly in the compensated form, yet a wide pattern of laboratory tests showed normal profiles in only 4% of the cases. There was no evidence that antecedent hepatotropic diseases (especially viral hepatitis) in any way determined the severity of the histological changes in the biopsies. No conclusive evidenc of the presence of dietary deficiencies was observed in these cases. Further analyses of clinical and biochemical findings from this group showed that continuous ingestion of alcoh for an av. period of more than 10 yr. in an amount surpassing the daily rate of ethanol metabolism seems to be required for the development of severe liver damage. Greater daily consumption may decrease the time required for damage to the liver although there is no eviden for this. The individual capacity of alcohol metabolism (0.1 g/kg/hr., ± 33%) may determine any given person the amount which, taken continuously, will prove injurious to his liver.

7503 EFFECT OF CERTAIN ANABOLIZING STEROID ON THE IN VITRO CONJUGATION OF BSP WITH GSH IN RAT LIVER. (It.) Di Toro, R. (U. Naples, Italy), L. Lupi, V. Ansanelli and A. D'Angelo. Epatologia 12(4):757-762, 1966.

Among virgin female Wistar rats weighing approx 250 g at the start of the experiment and treate with 19-nortestosterone phenylpropionate, 500 μg/dose, i.m. every 5 days for 1 mo., the mean percentage of BSP bound to reduced glutathione in the liver was 66.9%, with a range of 60-74% (controls; 51.6%, with a range of 46-59%). Among another group treated with 4-chlortestosterone acetate, 1 mg/dose, i.m. every 5 days f 1 mo., the mean percentage of BSP bound to redu glutathione was 55%, with a range of 49-61% (co trols: 42%, with a range of 36-46%). Among 4 the animals treated with 19-nortestosterone phenylpropionate, the total reduced glutathione content of the liver ranged from 0.35-1.74 mg/g fresh tissue (mean, 0.8725 mg/g); among 4 contr it ranged from 1.13-2.20 mg/g (mean, 1.595 mg/g Some degree of damage to liver cells was seen in almost all treated animals which were examin consisting of a spongy appearance of the cytoplasm and varying degrees of vacuolization, up to and including a total loss of cytoplasm accompanied by pyknosis and/or chromatolysis of the nuclei. However, such damage was limited t the interlobular regions and relatively restric zones of the parenchyma close to the centrilobu vein. In no case was there any significant alteration of hepatic lobular architecture.

7504 DECREASED RESPONSE OF BLOOD PRESSURE TO SYNTHETIC ANGIOTENSIN II IN RATS WITH CCl_4-INDUCED LIVER CIRRHOSIS. (Ger.) Dal Palù, C. (U. Padua, Italy), R. Miori, Zuin and F. Dornetti. Med. Pharmacol. Exp. sel) 16(3):245-250, 1967.

te rats (120 g initial wt.) were chronically soned by inhalation of CCl_4 vapor, admin. ce daily for a wk., then once/day for 11 mo. od pressure was measured at intervals; od pressure was also measured before and er i.p. inj. of angiotensin II (0.2 ml of a sh soln. in 5% glucose containing 0.04 μg; . was by a microsyringe). Blood pressure was en 3-8 times 1'30"-4'30" after inj. and the ues av. The pressures were taken using a f placed about the base of the tail with a nsducer recording on a direct-writing electro- diogram. During 0-2 mo. the chronically- soned rats showed an av. increase of systolic ssure of + 13.1 ± 1.2 mm Hg when inj. with iotensin; the controls had an av. increase er inj. in this period of + 12.1 ± 1.4 mm Hg; difference was not significant. In the in- val from 3-11 mo. the chronically-poisoned s showed an av. increase of systolic blood ssure after inj. of only + 0.29 ± 0.8 mm Hg; av. increase for the controls from 3-11 mo. + 9.74 ± 1.9 mm Hg. This difference was hly significant. The pressures before inj. angiotensin in both groups were essentially same in early and late periods. This effect ch is not seen in acute intoxication tends appear in the early stage of fatty infiltra- n, before proliferation of connective tissue apparent in the liver. It has been observed t patients with icterogenic hepatitis and se with ascitogenic cirrhosis are more sus- tible to angiotensin than earlier or less te forms. The cause is unknown. The experi- tal results seem to exclude tachyphylaxis ards angiotensin.

5 HISTOCHEMICAL AND ELECTRON MICROSCOPE FINDINGS IN ENLARGED LIVERS INDUCED BY EIGN SUBSTANCES IN WHITE MICE. (Ger.)

aude, G. (U. Marburg/Lahn, Germany), M. Siess, /ogell and J. Niessing. Acta Histochem. na) 26(1):185-201, 1967.

ogether 300 male mice were divided into ups of 20-30 animals for each conc. of each stance used; each experimental group was ched with a control group. Substances, ges and duration of admin. employed were: Phenobarbital, 100 mg/kg/day, i.p., 1-4 wk.; mg/kg/day p.o., 2 wk. (2) Thiopental, 60-100 g/day, s.c., 4 wk. (3) Halothane, 1% in ired air, 60 min. exposure/day, 4 wk. (4) vapor in respired air on 2 or 3 occasions, and vapor conc. not stated, but 25% of the als died of CCl_4 poisoning. (5) Combined thane and thiopental; halothane, 0.7% in ired air, 60 min. exposure and thiopental 00 mg/kg/day, s.c. 4 wk. Animals were killed ecapitation, the liver excised, weighed and ied. The glycogen content was within phy- ogical limits in both groups of substances biturates and halogenated hydrocarbons); fatty degeneration was much more marked after halothane and CCl_4 than after barbiturates. In strongly hypertrophied livers the blood vascular system was engorged with increased vascularization in response to the greatly increased vol. of parenchyma. Phenobarbital caused a large increase in the endoplasmic reticulum which was much swollen and vesiculated. Livers exposed to halothane, on the other hand, showed great increase in the size of mitochondria through swelling. In the livers affected by halothane fatty infiltration was marked, the animals treated by both phenobarbital and halothane showed a combination of the effects produced by each substance.

7506 THE INFLUENCE OF ADRENERGIC β-BLOCKADE ON THE CHLOROFORM-INDUCED FAT DEPOSITION IN THE LIVER. (Ger.)

Estler, C. J. (U. Erlangen-Nuremberg, Germany) and H. P. T. Ammon. Z. Ges. Exp. Med. 142(2):117-122, 1967.

Fasted white mice were grouped as: 1) controls, untreated, 2) CCl_4-treated animals: respired 1 vol.% CCl_4 for 2 hr. in a closed system, 3) CCl_4-treated animals inj. s.c. with 50 mg/kg 1-(isopropylamino)-3-(m-toloxy)2-propanol.HCl, a β-sympathicolytic agent, 0.5 hr. prior to CCl_4 treatment, 4) mice inj. with 50 mg/kg of the propanol, s.c., no other treatment. All mice were killed by decapitation and the blood collected 2.5 hr. after inj. or after 2 hr. exposure to CCl_4 vapor. The livers were also excised and frozen. Blood serum was analyzed for free fatty acids, esterified fatty acids, free cholesterol, total cholesterol. Liver tissue was analyzed for esterified fatty acids and total cholesterol. These determinations showed that exposure to 1 vol.% CCl_4 increased the unesterified fatty acids and decreased the esterified fatty acids in serum while increasing the esterified fatty acids in liver tissue. Pretreatment with the propanol derivative hindered lipolysis and the increase of the fat content in the liver, but did not prevent the decrease of fatty acid esters in the serum. These findings suggest that CCl_4-induced lipolysis in the serum and deposition of fat in the liver are mediated by catecholamines.

7507 STUDIES ON THE MECHANISM OF ENZYME INDUCTION. X. BARBITAL ACTION ON THE SUBSTRUCTURE OF LIVER CELLS OF DIFFERENTLY AGED RATS. (Ger.)

Franke, H. (U. Jena, Germany) and W. Klinger. Acta Biol. Med. German. 18(1): 99-119, 1967.

Infant rats received sodium barbital (150 mg/kg/day, i.p.) on days 3, 4, and 5 of life for some and on days 7, 8, and 9 for others; a 12-mo.-old male rat was inj. with sodium barbital (150 mg/kg/day, i.p.) on 3 successive days. The animals were killed on the sixth and tenth days and at 12 mo. and the liver tissue examined by electron microscope at 6300 to 42,000 magnification. The induction of multiplication of smooth membranes in the cytoplasm of liver cells was evident in 6- and 10-day rats treated with sodium barbital; the multiplication of the smooth membranes at 6 days was relatively poor; at 10 days, however, the smooth membranes were much more in evidence, attaining the adult condition in some of the cells. By contrast no multiplication of smooth membranes was observed in the liver cells of the 12-mo.-old male rat. In other individual single liver cells of the sodium barbital-treated animals signs of damage were evident, (swollen, partly destroyed mitochondria, and an ~~atypical~~, finely vesiculated endoplasmic reticulum without increase of smooth membranes). The glycogen granules were distinctly diminished or entirely lacking. Giant mitochondria were observed in some of the cells which showed multiplication of the smooth membranes. There were increased numbers of the "dark liver cells" in the sodium barbital-treated animals; these have been observed in livers having an increased growth rate such as in the newborn and in regenerating livers marking an increased protein synthesis, an active metabolism in conjunction with an increased rate of proliferation.

7508 STUDIES ON LEUCINE AMINOPEPTIDASE IN EXPERIMENTAL HEPATOBILIARY DISORDERS. (Jap.) Makiura, O. (Nara Med. U., Japan). Nara Igaku Zasshi (J. Nara Med. Ass.) 18(1):117-135, 1967.

Leucine aminopeptidase activity in the liver was histochemically studied in parallel with the biochemical determination of enzyme activity in the serum and liver in rats with experimental hepatobiliary lesions. In rats treated with CCl_4, the enzyme activity was markedly increased in the serum, while it was decreased in the liver. Histochemically, no enzyme activity was found in the necrotic regions in the liver, suggesting the release of the enzyme from these regions to the serum. In rats with ligature of the common bile duct, the enzyme activity in the serum was slightly increased, while that in the serum was unchanged through the fourth day after the ligature. High enzyme activity in the bile was noted in cases with high activity in the serum. The gradual increase of enzyme activity in both the serum and liver was found in rats maintained on α-naphthyl isothiocyanate, besides proliferation of the bile ductules, which were found histochemically to be abundant in enzyme activity. In rats fed 3'-methyl-4-dimethylaminoazobenzene, high activity and dense distribution of the enzyme were shown histochemically in the liver fibrosis stage, corresponding to the gradual increase of activity in the serum and liver. A more marked increase in activity in the serum was observed in the hepatoma stage as compared with that in the fibrosis stage. High enzyme activity was shown histochemically in cancer tissue.

7509 STUDIES ON THE MECHANISM OF THE ELEVATION IN SERUM ALKALINE PHOSPHATASE CTIVITY IN THE EXPERIMENTAL HEPATOBILIARY DISORDERS. WITH SPECIAL REFERENCE TO THE SERUM AND LIVER ALKALINE PHOSPHATASE ACTIVITIES ON THE BASIS OF THE HISTOCHEMICAL INVESTIGATION OF THE ENZYME IN THE LIVER. (Jap.) Nishi, T. (Nara Med. U., Japan). Nara Igaku Zasshi (J. Nara Med. Ass.) 18(1):137-153, 1967.

Histochemical studies were done on the activity and distribution of alkaline phosphatase in the liver of rats with experimental hepatic disturbances, in parallel with biochemical studies of the enzyme activity in the serum and liver. In rats treated with CCl_4, an increase of enzyme activity in the serum and liver was observed. Histochemically, no enzyme activity was found in the necrotizing liver cells while higher activit was found in the remaining normal cells as compa with that in the liver cells in the control; the facts suggest the release of the enzyme during t process of necrosis. In rats with ligature of the common bile duct, a marked increase of the enzyme activity was found in both the serum and liver. The highest activity throughout the stu and uniformly dense distribution of the enzyme was shown histochemically in the liver, especial along the bile capillaries and dilated bile duct and the diffusion of the enzyme from the bile d into the neighboring Glisson's sheath was noted. Feeding of α-naphthyl isothiocyanate induced an increase of the enzyme activity in the serum an liver, and histochemical studies revealed marke enzyme activity in the proliferating bile ductu and liver cells. During feeding, mild depletio of enzyme activity in both the serum and liver was temporarily noted, presumably due to the zonal difference in enzyme distribution or reduced enzyme formation in the atrophied or degenerated liver cells. Feeding of 3'-methyl-4-dimethylaminoazobenzene induced less increase i the enzyme activity in the serum and liver than the former treatments. During the course of fee-ing, the serum enzyme activity first increased, then decreased, and increased again. Prolifera of the connective tissue had no relation to increase of the serum enzyme activity in the stag of liver fibrosis induced by the feeding, while the hepatoma cells which were induced, had high enzyme activity.

7510 INFLUENCE OF HYDRAZINE ON THE DISTRIB TIONS OF FREE AMINO ACIDS IN MOUSE LIVER. (E.) Simonsen, D. G. (City of Hope Med Ctr., Duarte, Calif.) and E. Roberts. Proc. So Exp. Biol. Med. 124(3):806-811, 1967.

Using two-dimensional paper chromatography, the amino acid pattern in the liver of rats given hydrazine inj. (3 mM/kg) 30 min. after i.p. inj of saline, arginine, alanine, glutamic acid or mixture of all 3 acids in equal parts showed in-creased quantities of citrulline which were not reflected in the urine or other tissues. Inj. of arginine, alone or in combination with alani and glutamic acid, followed by hydrazine admin. resulted in marked increase in levels of ornith and smaller elevations in glycine, serine and threonine levels as compared to rats treated wi

ydrazine alone, and no increase in glutamic
d aspartic acid components. Protection against
ydrazine toxicity was enhanced when all 3 acids
ere given. No evidence of argininosuccinic
id accumulation in the liver was observed,
ggesting that hydrazine operates at the con-
nsation point of citrulline and aspartic acid,
ich may be rate-limited itself.

11 CHEMICAL, HISTOLOGIC AND IMMUNOLOGIC
RESPONSES IN RATS TO CCl_4. II.
LATIVE INFLUENCE OF CHOLINE DEFICIENCY. (E.)
dson, V. N. (U. Michigan, Ann Arbor), D. F.
tchum and R. De Mott Friberg. Proc. Soc. Exp.
ol. Med. 124(3):966-969, 1967.

le albino Sprague-Dawley rats were divided into
groups: 1) normal controls fed a regular
et; 2) and 3) those fed a choline-deficient
et for 2 or 4 wk. before exposure to CCl_4 (0.25-
50 ml) and 4) those fed a regular diet but
posed to CCl_4. The lipid and hydroxyproline
ntent and histology of the livers were studied;
d antiliver factors were determined by hemag-
utination and precipitin methods and skin tests
ilizing extracts prepared from normal and
l_4-exposed (single 0.25 ml s.c. inj. 4 hr.,
hr. or 5 days beforehand) rats. Deficiency
choline produced the greatest lipidosis in
e liver and was associated with a high pre-
lence of antiliver serum factors by hemagglu-
nation. The degree of lipidosis was related
the duration of choline deficiency; 6 wk.
choline deficiency produced a mean liver lipid
nc. of 75.3%, compared to 38.4% with a 4-wk.
oline deficiency and 11.6% for normal controls.
l_4 influenced these parameters very little
der the conditions of these experiments.

12 ALTERATIONS IN MICROSOMAL ELECTRON
TRANSPORT, OXIDATIVE N-DEMETHYLATION
D AZO-DYE CLEAVAGE IN CARBON TETRACHLORIDE AND
METHYLNITROSAMINE-INDUCED LIVER INJURY. (E.)
uckler, E. A. (U. Washington, Seattle), E.
rhenius and T. Hultin. Biochem. J. 103(1):
-64, 1967.

e effect of admin. of CCl_4 (0.25 ml/100 g body
. dissolved in an equal vol. of mineral oil)
d dimethylnitrosamine (2 ml/100 g body wt.,
ssolved in water) in vivo on hepatic microsomal
nction related to drug metabolism was measured
male Sprague-Dawley rats. The capacity of
olated microsomes to demethylate dimethylaniline
s diminished during the first hr. after CCl_4
isoning and during the second hr. after dimethyl-
trosamine poisoning. Thereafter the microsomes
om CCl_4-poisoned livers showed a continuous
cline in activity so that at 24 hr. there was
ttle residual capacity to undertake demethyla-
on. Microsomes from dimethylnitrosamine-
isoned rats were not different from controls
24 hr. During the first 3 hr. there was a
ansient rise in the accumulation of the N-oxide
termediate in CCl_4-poisoned livers, with a
subsequent fall to below control values. In dimethylnitrosamine poisoning there was a parallel decrease in N-oxide accumulation with decreased demethylation. In the latter part of the first 24 hr., the ratio of N-oxide accumulation to demethylation was increased in both instances. There was no evidence of altered reduced nicotinamide adenine dinucleotide phosphate-dependent neotetrazolium reduction or lipid peroxidation at 2 hr. after poisoning with either compound. Reduced nicotinamide adenine dinucleotide phosphate-dependent azo-dye cleavage was decreased. There was no difference in microsomal cytochrome b_5 content, but there was a decrease in the amount of cytochrome P-450; this latter change was correlated with the decreased capacity for reduced nicotinamide adenine dinucleotide phosphate-dependent oxidative demethylation. It is suggested that dimethylnitrosamine is associated with a defect in microsomal reduced nicotinamide adenine dinucleotide phosphate-dependent electron transport at the level of cytochrome P-450. CCl_4 is associated with a second severe block involving the release of formaldehyde from the N-oxide intermediate, in addition to affecting cytochrome P-450.

7513 THE EFFECT OF THE AFLATOXINS B_1, G_1 AND G_2 ON PROTEIN AND NUCLEIC ACID SYNTHESIS IN RAT LIVER. (E.) Clifford, J. I. (Univ. Coll. Hosp. Med. Sch., London), K. R. Rees and M. E. M. Stevens. Biochem. J. 103(1): 258-261, 1967.

The interaction of aflatoxin G_1 and G_2 with calf-thymus DNA (1.99 mM) was compared with that of aflatoxin B_1 (conc. of each toxin was 64.0 μM); changes in difference spectra of G_1 and G_2 were considerably smaller than those with B_1. The effect of a range of conc. of the various aflatoxins was tested on the incorporation of [^{14}C]-orotic acid into the RNA of the liver slices prepared from control rats; B_1 produced a much greater inhibition than G_1 and G_2. The effect of the various aflatoxins on the incorporation of DL-[1-^{14}C]leucine into the proteins of rat-liver slices was also studied (conc. of toxin in mμmoles in 3 ml; aflatoxin and % inhibition were, resp.: B_1, 20 and 40, 32% and 55%; G_1, 150 and 300, 35% and 62%; and G_2, 230 and 460, 38% and 83%); the different conc. of the toxins used produced an inhibition of the same order in amino acid incorporation into the proteins of the liver slice. The effect of aflatoxin B_1 on the RNA-polymerase activity of liver-cell nucleoli was studied in 2 experiments; each reaction mixture in the first experiment contained all the nucleoli isolated from 1 rat liver and such a preparation gave an active incorporation of nucleotide into the nucleolar RNA; addition of several conc. of B_1 to the nucleolar preparation in vitro was without effect. In the second experiment, rats were poisoned with twice the LD_{50} of aflatoxin B_1 (14 mg) dissolved in dimethylformamide and control rats received the latter alone; there was a marked inhibition in the RNA polymerase of the nucleoli prepared from the livers of the poisoned rats. The extent of the inhibitory action of the aflatoxins on the synthetic reactions was proportional to the degree of spectral shift obtained with their interaction with DNA; coupled with the studies on protein synthesis it is concluded that the toxic action of the aflatoxins is related to their interaction with DNA and that their degree of interaction determines their degree of toxicity. The demonstration of inhibition of RNA polymerase after aflatoxin B_1 poisoning was regarded to be further evidence that inhibition of nuclear RNA synthesis in aflatoxin B_1 poisoning was due to the toxin interacting with DNA, and thereby preventing a transcription of the DNA.

7514 A DECREASED PRODUCTION OF PORPHYRINS AND VARIATIONS IN THE HEPATIC AND ERYTHROCYTE CONCENTRATION OF ATP DURING ACUTE ALCOHOL INTOXICATION IN THE RAT. (Fr.) Gajdos, A. (Hotel Dieu, Paris), M. Gajdos-Török, A. Palma-Carlos and L. Palma-Carlos. Nouv. Rev. Franc. Hemat. 7(1):15-26, 1967.

When female white rats were admin. 3 i.p. inj./day of 7.5 ml/kg of 33% alcohol for 8 days, the porphyrin metabolism was altered in the following manner: increases were seen in the urinary excretion of porphobilinogen and uroporphyrin and in the level of ether-soluble porphyrins in the liver and red blood cells. In addition, this intoxication caused an important and early decrease in the hepatic level of adenosine triphosphate (ATP) and, less constantly, the accumulation of reduced diphosphonucleotide (DPNH) in the hepatic tissue. An increase in reticulocytosis and in the ATP conc. in the circulating RBC was also seen, as well as a slight but statistically significant anemia. When daily doses of adenosine monophosphate (AMP, 20 mg, i.m.) were admin. simultaneously with the alcohol these biochemical irregularities in porphyrin metabolism were improved in the liver but the high levels of free porphyrins and of ATP in the RBC were not altered. In addition, neither the anemia nor the reticulocytosis was altered by the AMP treatment. When 15 ml/kg was admin. for 2 days, in those animals which survived this strong intoxication, a decrease in the AT and an increase in the ether-soluble porphyrins, total lipids, DPN and DPNH in hepatic tissue was seen. These factors were also observed only 2 days after 7.5 mg/kg; however the RBC changes had not yet occurred. These data indicate that alcohol intoxication alters 2 modes of porphyrinogenesis; that in the liver by decreasing ATP formation and that in the bone marrow by erythropoietic hyperfunction.

7515 CARBON TETRACHLORIDE EFFECT ON LIVER AUTOTRANSPLANTS WITH TOTALLY REVERSED BLOOD FLOW. (E.) Sigel, B. (Women's Med. Coll., Philadelphia, Pa.), L. B. Baldia, M. R. Dunn and M. E. Dimbiloglu. Nature (London) 213(5082) 1258-1259, 1967.

Following transplantation of the left lateral lobe of the canine liver to the right side of the neck by either "straight" (12) or "reverse" (11) blood flow technic, single i.m. inj. of CCl (0.5 ml/kg body wt.) were admin. 1-23 days after graft establishment. Grafts and residual livers were removed 24 hr. after inj. Tissue preparations of nontransplanted liver showed uniform centrilobular necrosis and lipid accumulation. The general pattern of injury in "straight" blood flow preparations resembled that of nontransplanted livers and was probably the result of the grafting procedure. A similar but more pronounced pattern of central necrosis and lipid accumulation was observed in the "reversed" bloo flow autografts. In the "reversed" group, atrophic alterations due to the grafting procedure increased with the age of the transplant. The results of this experiment present evidence against the hypothesis that the CCl_4 effect on the liver is the result of ischemia.

7516 THROMBOPLASTIN ACTIVITY IN LIVER HOMOGENATES FROM RATS POISONED WITH CCl_4. PRELIMINARY NOTE. (It.) Panputi, F. (U. Bologna, Italy), G. Facchini and G. P. Cremonini. Arch. Path. Clin. Med. 43(2):153-156 1966.

CCl_4 in olive oil (ratio = 1:2; dose = 0.10 ml/100 g, s.c., single dose) was admin. to albin rabbits weighing an av. of 3.2 kg, 12 hr. prior to sacrifice. Quick time in liver homogenates ranged from 30"-37" (mean = 33.5"), as compared to a range of 35"-40" (mean = 37.3") in controls It is suggested that the difference may have resulted from increased lipid content in the livers of intoxicated animals.

7517 EFFECTS OF WHOLE BODY IRRADIATION WITH GAMMA RAYS ON CYSTATHIONASE ACTIVITY IN RAT LIVER. (It.) Moschini, G. B. G. Med. Milit. 116(6):810-817, 1966.

Male Wistar rats weighing approx. 270 g were subjected to varying total amounts of whole-body gamma irradiation, using ^{60}Co as a source and an exposure rate of 70 r per min. In animals receiving 200 r total dose, cystathionase activi in liver homogenates increased progressively to peak at +63% at 48 hr., then decreased to -1% over the next 30 days. In rats receiving 600 r total dose, it decreased progressively to a negative peak of -65% at 48 hr., then increased progressively to reach -9% at the end of the nex 30 days, which was also the end of the observation period. In rats receiving 1000 r, the LD_{100}, it decreased progressively to reach a negative peak of -76% at 48 hr.; recovered to -68% by day 8. On days 12, 16, 24 and 32, it was -76%, -75%, -73% and -73%, resp. It is suggested that the increase of activity demonstratec

response to a total dose of 200 r may have
sulted from increased synthesis of the enzyme,
e to a radiation-stimulated increase of cysteine
tabolism.

18 PHOSPHOLIPID CHANGES DURING HEPATIC INJURY CAUSED BY CARBON TETRACHLORIDE.
.) Sgoutas, D. S. (U. Illinois, Urbana).
tabolism 16(4):382-391, 1967.

le Sprague Dawley rats were starved overnight
d CCl_4 in liquid paraffin (1:1, v/v) was admin.
.5 ml/100 g body wt.) under ether by a stomach
be. Paired controls received 0.25 ml paraf-
n/100 g body wt. All rats were killed 4 hr.
ter treatment, their livers removed, and total
oid extracted. The phospholipid fraction, which
uted with 9% methanol in chloroform on silic
d column chromatography, was hydrolyzed with
kali and the hydrolysis products were subjected
ion exchange chromatography. Phosphatidyl
ycerol was increased 4-fold, and was now a
gnificant component. Phosphatidic acid in-
eased slightly as did phosphatidyl inositol and
e combined sphingomyelin and lysophosphatidyl
oline fraction. Cardiolipin and phosphatidyl
oline remained essentially unchanged, while
osphatidyl serine and phosphatidyl ethanolamine
creased, the latter considerably. Treatment of
ts with CCl_4 caused a considerable reduction
the polyunsaturated fatty acid content of
ospholipids.

9 ORAL CONTRACEPTIVES AND LIVER DAMAGE.
(E.) Sotaniemi, E. (U. Oulu, Finland)
P. A. Järvinen. Excerpta Med. Int. Congr.
. 118 8:208-212, 1967.

jects, 10 postmenopausal women (54-72 yr.-old)
h no history of liver complaints and normal
er function tests at the time of study,
eived estrogen (0.010 mg ethinylestradiol
ly), progesterone (5 mg lynestrol daily on
s 7-28 of menstrual cycle), and a second pro-
terone (5 mg dydrogesterone daily during days
68). Laboratory tests were made at fixed in-
vals: SGOT, SGPT, serum alkaline phosphatase,
mol turbidity, serum bilirubin, and BSP reten-
n (45 min. after i.v. inj. 5 mg/kg BSP). Be-
se of bleeding, 5 subjects discontinued the
lets after 28 days. Bilirubin, alkaline
sphatase, and thymol turbidity levels remained
stant during the study. After 7 days, 4 women
wed increased BSP retention; after 21 days, 7;
most returned to normal, only 1 remaining
vated at 68 days. SGPT was increased after 7
s in 2; after 21 days in 7; after 28 days in
SGOT was increased in 1 after 7, 21, and 28
s. Estrogen alone produced slight changes
ch were first strengthened by progesterone,
in 28 days some adaptation to hormone activa-
n seemed to occur. This was based on the
ardation of hormone inactivation in postmeno-
sal women. Women with a history of disturbed
atic function may be predisposed to jaundice
er admin. of oral contraceptives.

7520 ENZYME HISTOCHEMICAL INVESTIGATIONS OF THE INHIBITORY EFFECT OF ZINC ON THE INJURIOUS ACTION OF CARBON TETRACHLORIDE ON THE LIVER. (E.) Saldeen, T. (U. Lund, Sweden) and U. Brunk. Frankfurt. Z. Path. 76(4):419-426, 1967.

Liver damage was produced in 20 g white male mice by i.p. inj. of 0.01 ml CCl_4. Twelve hr. before inj. and 12 and 36 hr. after inj., mice received a dose of 0.2 ml $ZnCl_2$ in saline (1 mg/ml) s.c. They were decapitated 48 hr. after inj. of CCl_4. Liver changes were studied histologically, histochemically and biochemically. Mice receiving CCl_4 and $ZnCl_2$ showed a greater increase in alkaline phosphatase activity in the regenerating peripheral zone of liver lobules than those treated with CCl_4 alone. This was not observed with acid phosphatase or esterases. Increased frequency of mitotic figures in this region suggested that the protective effect of Zn may be partly due to activation of alkaline phosphatase during the regeneration phase. With the admin. of Zn alone, there was no observed increase in alkaline phosphatase peripherally. That no differences were found between Zn-dependent and Zn-independent enzymes after admin. of Zn suggests that the protective effect was most likely not due to an activation of Zn-dependent enzymes.

7521 EXPERIMENTAL ALLERGIC HEPATITIS. CORRELATION BETWEEN THE MORPHOLOGICAL CHANGES AND LIVER FUNCTION. (E.) Hamamoto, Y. (Osaka Med. Coll., Japan). Acta Path. Jap. 16(3): 287-299, 1966.

Six rabbits were sensitized against bovine RBC by i.v. inj. of 5 ml of a 5% suspension of bovine RBC until the hemolysin titer of rabbit serum against bovine RBC was 1:1280. A provocative inj. of a 20% saline suspension of bovine RBC was admin. by portal vein or hepatic artery. Controls were sensitized rabbits without provocative inj. and untreated rabbits inj. with a single dose of bovine RBC. Liver function tests were: total serum protein and serum protein electrophoresis; icterus index; Co-reaction; cephalin-cholesterol flocculation test; thymol reaction; Rugol reaction; Takata reaction. Rabbits showed focal necrosis of hepatic cells, exudates around the portal vein, portal thrombosis, fibrinoid swelling of the wall of the hepatic artery. Biochemical tests showed only slight damage of liver function. There was no difference whether inj. was by portal vein or hepatic artery. For reversed anaphylaxis 24 rabbits received an i.v. inj. 1.5 ml of anti-rabbit RBC guinea pig serum (hemolytic titer 32-64) in the hepatic artery or portal vein. Controls were rabbits inj. with normal guinea pig serum. Liver changes, similar but more extensive than above, were thought to be due to intravascular fibrin deposition. Functional tests showed more severe damage until a basic similarity with human liver cirrhosis was noticed. There were no significnt changes in controls. It is suggested that anaphylaxis may be implicated in the etiology of human hepatitis.

7522 EFFECTS OF NUCLEIC ACID PRECURSORS ON LIVER INJURIES. I. TREATMENT OF LIVER INJURY INDUCED BY LOW PROTEIN, AMINO ACID IMBALANCED DIET WITH AICA AND AICA OROTATE IN MASSIVE DOSES. (E.) Hashimoto, S. (Western Reserve U., Cleveland, Ohio). J. Vitamin. (Kyoto) 13(1):9-18, 1967.

Rats were maintained on a low protein and amino acid imbalanced diet for 11 wk. to induce fatty livers and were then divided into 3 groups: 1) received a 20% casein diet (controls); 2) the same diet plus 1.6 g/kg body wt. daily of 1% 4-amino-5-imidazolecarboxamide (AICA); 3) the same diet but 3.2 g/kg body wt. of 2% AICA orotate daily, for 4 additional wk. Some were killed at 3, 5, 7, 9, 11, and 15 wk. for study. Low protein increased liver phospholipid slightly and neutral lipid and cholesterol ester fractions markedly. With 20% casein, increase in neutral lipid and cholesterol continued in Group 1, but not in 2 or 3. The iodine number of liver fatty acid gradually increased with low protein diet, especially in neutral lipid and cholesterol ester fractions. In Group 1, the iodine number in phospholipid tended to recover, while those in neutral lipid continued to decrease. In Groups 2 and 3 the iodine number in phospholipid increased less than, but those in neutral lipid increased more than in Group 1. Low protein diet caused liver fibrogenesis, which was inhibited by AICA orotate, while AICA ahd an inhibitory effect on recovery of fibrosis. There was no difference in liver protein between the 3 groups after feeding with 20% casein diet. Serum ornithine carbamyl transferase rose on low protein and decreased in all groups on 20% casein. Vacuolar degeneration, which developed on low protein, was reduced on 20% casein. The low protein decrease in Palade granules was reversed in all groups on 20% casein. It is suggested that AICA not be used alone, to prevent metabolic imbalance of nucleic acids.

7523 THE 2 HOUR SULFOBROMOPHTHALEIN RETENTION TEST AND THE TRANSAMINASE ACTIVITY DURING ORAL CONTRACEPTIVE THERAPY. (E.) Larsson-Cohn, U. (Univ. Hosp., Uppsala, Sweden). Amer. J. Obstet. Gynec. 98(2):188-193, 1967.

The subjects were 22 student nurses (21-26 yr.), all but 1 of whom were unmarried and nulliparous. Ten used Conluten (2 mg norethindrone plus 0.1 mg ethinyl estradiol-3-methyl ester; 21 days of 28), 5 received Volidan (4 mg megesterol acetate plus 0.05 mg ethinyl estradiol; days 5-24), 1 received Anconcen (3 mg chlormadinone acetate plus 0.1 mg ethinyl estradiol-3-methyl ester; 21 days of 28), and 1 received Lyndiol mite (2.5 mg Lynestrol plus 0.075 mg ethinyl estradiol-3-methyl ester; 22 days of 28). All 5 Volidan patients switche to Conluten because of breakthrough bleeding. Serial determination of BSP retention (2 hr. after inj. of 20 mg/kg body wt.), SGPT, and SG were made on subjects before, during, and afte 1 yr. on oral contraceptives. Increased dye r tention (2% or more) was observed in 16 subjec and in 44% of all dye tests performed during t study. Six had elevated SGOT values, 11 eleva SGPT. The frequency of elevated transaminases reached max. after 1 mo. therapy and gradually decreased, while frequency of dye retention reached max. after 3 mo. and remained constant There were observed similarities between signs of abnormal liver function observed during ora contraceptive therapy, in the last trimester o pregnancy, and with idiopathic jaundice of pre nancy. There were 3 cases of toxic reaction t BSP. Despite the increased sensitivity of the modified method, 2-hr. dye retention tests are not recommended for similar situations.

7524 PERSISTENT BINDING OF BUTTER YELLOW METABOLITES TO RAT LIVER DNA. (E.) Warwick, G. P. (Roy. Cancer Hosp., London) and J. J. Roberts. Nature (London) 213(5082):1206 1207, 1967.

Metabolites of radioactive butter yellow, (^{3}H- dimethylaminobenzene, specific activity 1.2 cpmmole) were found to bind covalently to live DNA when injected i.p. (150 mg/kg) into 18 Chester Beatty rats (200 g). A study to deter the half-life of DNA-associated radioactivity reported. The specific conc. of the radioacti decreased to half its initial value within 7 d The fact that it remained constant at this lev for 3 mo. suggested an absence of repair. Thi might explain chromosome aberration found in regenerating liver after treatment with carcin gens and may play a role in the latent period carcinogenesis.

7525 NUCLEOLAR CHANGE PRODUCED BY MITHRAM IN RAT HEPATIC CELL. (E.) Kume, F. (U. Utah Coll. Med., Salt Lake City), S. Maruy A. N. D'Agostino and M. Chiga. Exp. Molec. Pa 6(2):254-260, 1967.

One-mo.-old rats (70-90 g) were inj. i.p. with mithramycin (30 µg/100 ml), dissolved in 0.85% saline, and were killed after 30 min. Mithram conc. was determined spectrophotometrically. electron microscopy, tissue was fixed in phosp buffered 1% osmium tetroxide at 4°C, dehydrate in ethanol, embedded in Epon 812, and stained with lead citrate. Nucleoli were examined by light microscopy with azure C supravital stain To estimate % of hepatic parenchymal cells sho ing nucleolar change, 200 cells in the smear were examined. The approx. dose required to p duce nucleolar change in more than 95% of hepa parenchymal cells was determined by the method Deichman and LeBlanc. Mithramycin caused a "r distribution" or "sorting out and coalesence"

cleolar components, similar to that produced
actinomycin D. Coarse granules and fibrillar
mponents were grouped separately. Mithramycin
so caused a separation of the azurophilic and
nazurophilic components, called "nucleolar
rtition". One day after inj. nucleoli of
patic cells showed a normal reticulated pattern,
d hence the nucleolar partition was considered
versible. At the above dose, incomplete par-
tion was observed in 15-25% of the hepatic
lls, complete partition in 75-85%. The in-
bitory effect of mithramycin on DNA-directed
A synthesis is thought to be related to the
cleolar change.

26 EFFECT OF ALPHA-NAPHTHYL-ISOTHIOCYANATE
(ANIT) ON RAT LIVERS, STUDIED WITH
LCHICINE AND WITH ^{3}H-THYMIDINE AUTORADIOGRAPHY.
.) Ungar, H. (Hadassah Med. Sch., Jerusalem)
d I. S. Levij. Exp. Molec. Path. 6(2):232-236,
67.

Naphthyl-isothiocyanate was dissolved in olive
l (150 mg/ml) and 0.1 ml/150 g body wt. was
min. p.o. to 25 rats (10 mg/100 g). Rats were
lled in groups of 5 at 8, 26, 50, 98 and 170
. after admin. Two hr. before killing, all
ts received 1 µc ^{3}H-thymidine/g i.p. Thin
ices of liver were fixed in 10% neutral buffered
rmalin; 8-10 µ paraffin sections were coated
th Kodak NTB-3 emulsion and exposed at 4°C in
e dark for 4 wk.; autoradiographs were stained
th hematoxylin and eosin. In each the number
labeled cells was counted among at least 2000
patocytes, 1000 littoral cells, and 1000 ductal
lls. A nucleus was considered labeled if over-
in with at least 5 grains. In the colchicine
udy, 5 controls received no α-naphthyl-isothio-
anate; 25 received it in the above dose. Rats
re sacrificed on the same schedule as above,
cept that they received an i.p. inj. of 0.2
/g of a 0.1% soln. of colchicine in physio-
gical saline 4 hr. before killing. Thin liver
ices were fixed in Zenker acetic acid and 6 µ
raffin sections were stained with hematoxylin
d eosin. In each rat the number of mitoses was
unted among at least 2000 hepatocytes and 1000
ctal cells. Mitoses among littoral cells could
t be differentiated. After admin. of drug,
nthesis of DNA and mitotic count were tem-
rarily decreased in all types of cells. Among
patocytes, the number of labeled nuclei was
ch smaller at 8 and 26 hr. after admin. than
controls. The number of labeled cells among
le duct epithelium was decreased at 8 hr., but
turned to control after 26 hr. No mitoses
re seen in bile duct epithelium at this stage.
A synthesis in liver cells and bile duct cells
owed a marked increase at 50 hr., and at this
age the number of mitoses and labeled cells
ong both cell populations reached a peak much
eater than normal counts. The increase in DNA
nthesis and mitotic counts among bile duct cells
ceeded that among hepatocytes. The mitotic
unts and the number of labeled hepatocytes and
le duct cells returned to control level by 98
hr. After an initial period of depression, DNA synthesis gradually increased among littoral cells. The marked increase in DNA synthesis and mitotic rate among ductal cells was correlated with a large increase in the number of bile ductules. The results support the theory that newly-formed bile ductules are derived from proliferation of pre-existing ductal epithelium.

7527 THE INCORPORATION OF PROLINE IN EXPERIMENTAL LIVER FIBROSIS. (Ger.) Becker, K. (U. Hamburg-Eppendorf, Germany). Acta Hepatosplen. (Stuttgart) 14(1):42-48, 1967.

White rats (200 g) were studied in 2 series: (1) 40 normal and (2) 16 treated with thioacetamide (0.02% thioacetamide) in the drinking water for 6 mo. After this period the livers of these animals exhibited a well-developed fibrosis. The animals received i.p. inj. of 1 µc ^{14}C-proline; 12, 24, 48, 72 hr. and 1 wk. after inj. the animals were killed by decapitation and bled; blood was washed out of the liver by a saline soln. inj. through the portal vein. Liver tissue, the xiphoid process, and the tail tendon were weighed (wet wt.), homogenized, and the radioactivity of aliquots determined by scintillation counter. The purity of the labeled proline had previously been established by chromatography. The amount of radioactive proline incorporated into the fibrotic livers was over twice that in normal livers. The incorporation of proline into the gelatin of the xiphoid process and the tail tendon reached a max. at 72 hr. The kinetics of collagen metabolism remains the same in normal and cirrhotic animals. The ^{14}C-proline incorporation is increased in liver fibrosis in proportion to the increased collagen content of the fibrosed liver.

7555 HUMAN AND ANIMAL EXPERIMENTAL STUDIES ON LIVER LOADING-AFTER NEUROLEPTIC ANALGESIA. (Ger.) Schellenberger, A. (U. Munich, Germany), A. Doenicke and T. Gürtner. Anaesthesiol. Resus. (Berlin) 18:8-16, 1966.

7556 INFECTIOUS HEPATITIS IN CHILDREN AND GAMMA-GLOBULIN. (Cz.) Hrdlickova, J. (Pediat. Inst., UDL, Prague). Cesk. Pediat. 21(10):871-875, 1966.

Of 3352 children up to 14 yr. old, affected during 1958-1962 in Prague by viral hepatitis, 412 were treated with human γ-globulin up to 3 mo. before the appearance of hepatitis symptoms. The severity of the hepatitis in γ-globulin-treated and untreated children was compared. The length of hospitalization was 16.1 and 14.4 days, the time required for the normalization of hepatitis tests 14.5 and 11.4 days, that for the normalization of urine tests 12.7 and 11.2 days, the duration of jaundice 11.6 and 7.8 days, and the max. levels of bilirubin in the blood 4.13 and 2.83 mg% in untreated and treated groups, resp. All these differences were statistically significant. However, the max. levels of transaminases, and the incidence of recurrences did not differ significantly in the 2 groups. Gamma-globulin was most effective when admin. 8-21 days before hospitalization, but its effect was clearly evident even when applied a few days before the appearance of hepatitis symptoms.

7557 TREATMENT OF VIRAL HEPATITIS IN CHILDREN. (Cz.) Bila, L. (Thomayerov Hops., Prague). Cesk. Pediat. 21(10):880-884, 1966.

The experiences of the authors with the treatment of children suffering from viral hepatitis are described. The children should be hospitalized immediately after the appearance of the first symptoms and rest in the bed until the blood bilirubin content decreases to 1.0-1.5 mg%, the level of transaminases becomes normalized, and the hepatosplenomagaly disappears. The diet should be rich in carbohydrates which can be easily metabolized, poor in fats, and should contain an amount of proteins appropriate to the age of the child. In children with diabetic complications the metabolic balance should be preserved, i.e. amounts of insulin admin. should not be altered. The period when the diet of children contains only carbohydrates should be shortened with these patients. The authors do not recommend treatment of patients with monosaccharides or amino acids. Antibiotics (neomycin, colistin, polymyxin) should be applied only in severe cases. Patients with prolonged and cholestatic forms of viral hepatitis were successfully treated with corticosteroids, especially with prednisone (0.5 mg/kg/day).

7558 THE USE OF CORTICOSTEROIDS AND LYSOZYME IN THE TREATMENT OF CHILDHOOD VIRAL HEPATITIS. (It.) Maggi, M. (C. Arrigo Child. Hosp., Alessandria, Italy) and G. Fossati. Minerva Pediat. 18(33):1958-1960, 1966.

Among 10 children with viral hepatitis, treatmer with lysozyme (15-20 mg/kg/day, p.o.) led to normalization of bilirubinemia in an av. of 19 days, normalization of SGOT and SGPT levels in an av. of 16. Among 13 children receiving the same treatment plus betamethasone (0.1-0.2 mg/kg/day, usually p.o.) the times required for normalization as above were 17 and 17 days, resp Among 23 receiving betamethasone alone, the time required were 18 and 19 days, resp. The 3 patie groups, combined, consisted of 19 boys, 27 girls aged 21 mo.-12 yr. Although no statistically significant differences are shown among the 3 groups, it is suggested that the combined treatment indicated was probably the therapy of choice.

7559 ANABOLIZING STEROIDS IN THE TREATMENT OF VIRAL HEPATITIS. (It.) Tolentino, P. (U. Genoa, Italy). Epatologia 12(3):462-470, 1966.

The mean number of days required to halve above-normal increases of values for serum bilirubin, SGOT, SGPT and MacLagan's Test were tabulated fo 26 children receiving conventional therapy for viral hepatitis, as follows: 8.6, 6.8, 6.9 and 17.8 days, resp. Comparable tabulations for 32 children receiving conventional therapy plus 4-chlortestosterone (0.5 mg/kg/day for 20 days) were: 7.2, 7.0, 6.6 and 12.3 days, resp.; for 12 children receiving conventional therapy plus 4-chlortestosterone as above plus prednisone (1 mg/kg/day for 20 days), they were: 6.1, 4.9, 5.0 and 15.6 days, resp. For 6 children receivi conventional therapy plus successive courses of demecolcine (3-6 mg/day x 3, i.v.), then prednisone (1 mg/kg/day for 3 days), then 4-chlortestosterone (0.5 mg/kg/day for 20 days) they were: 7.7, 3.3, 2.9 and 14.4, resp. Note is made that the improvements shown in 3 of 4 quadrants by the combination of prednisone with 4-chlortestosterone were not at a level of statistical significance; that those shown by the admin. of the 3 drugs in sequence, as concerned serum transaminase levels, approached statistical significance fairly closely.

7560 URIDINE DIPHOSPHOGLUCOSE IN THE TREATMENT OF VIRAL HEPATITIS. (It.) Pagliano Sassi, L. (Hosp. Inst., Milan, Italy) and A. Moreno. Epatologia 12(4):732-738, 1966.

A total of 91 patients of both sexes (5-71 yr. old), took part in a comparative study of 4 therapeutic trials for viral hepatitis. Among 33 of 91 who received uridine diphosphoglucose (20-40 mg/day, i.v.; duration of treatment not indicated), serum bilirubin was normalized withi an av. of 19 days, transaminase levels within an av. of 16 days, clinical status within an av. of 21.3 days. Comparable tabulations for 14 of 91 who received the same treatment plus

ednisone (20-30 mg/day for 15 days, p.o.)
re 20.5, 17.7 and 22.8 days, resp.; for 22
91 who received prednisone along (in associa-
on with tetracycline and conventional therapy),
ey were 25.4, 25.4 and 25.7 days, resp.; for
of 91 who received conventional therapy alone,
ey were 25.2, 24.3 and 28 days, resp. It is
ncluded that uridine diphosphoglucose appears
be a useful addition to the agents available
treating this disorder.

61 TREATMENT OF VIRAL HEPATITIS IN THE
LIGHT OF MANY YEARS OF EXPERIENCE
PEDIATRIC PRACTICE. (It.) Segagni, E.
osp. S. Spirito, Casale Monferrato, Italy).
atologia 12(4):697-692, 1966.

ompt clinical and laboratory improvement was
tained in 40 of 40 children, 1-12 yr. old,
whom viral hepatitis was treated with
ednisone or betamethasone, although 2 of 2
her children failed to show similar response
treatment with dexamethasone. Prompt
sponses were also obtained in 10 of 10, aged
10 yr., who were treated with lysozyme for
days (125-250 mg/day, i.m. plus 100-300
/day, p.o.). Somewhat slower but equally
od results were obtained in 26 of 26, aged
12 yr., who were treated for 10-15 days with
sozyme (4 mg/kg/day, i.m.) plus xenalamine
enovis, 40 mg/kg/day, p.o.). In a correlative
udy, although 5 of 5 puppies used as controls
ccumbed to acute viral hepatitis, there were
mortalities among 4 of 4 who received
tamethasone (0.1 mg/kg/day, p.o.) plus
sozyme (125 mg/day, i.m. and 200 mg/day, p.o.)
us xenalamine (40 mg/kg/day, p.o.) for total
riods of 10-15 days. All the animals recovered
mpletely within a total observation period of
-40 days. It is concluded that all 3 medica-
ons were effective against the disorder and
at the use of all 3 in combination may be the
eatment of choice in severe cases, in the
sence of contraindications.

62 NEW EXPERIENCES MADE IN THE TREATMENT
OF ACUTE VIRAL HEPATITIS. THE EFFECT
CHOLINOROTATE. (Ger.) Wildhirt, E. (City
osp., Kassel, Germany) and H. Selmair. Munchen.
ed. Wschr. 109(16):887-891, 1967.

tients (99) with acute viral hepatitis
tablished by laboratory tests of serum
lirubin conc., protein lability, electrophore-
s, transaminase levels, and serum Fe conc.,
nd by biopsy in 14 cases, were treated with
ed rest, a high protein, low fat diet, hot
oplications in the region of the liver, and the
dmin. of 2 tablets of cholinorotate p.o. three
imes per day. Each tablet contained 500 mg
f cholinorotate (Cholergol), i.e., a combination
f orotic acid and choline. Animal experimenta-
ion showed a more rapid regeneration of damaged
iver tissue following cholinorotate therapy;
he return to normal of fatty livers under this

has also been observed. Among the patients with hepatitis, the tolerance to the substance was outstanding; no side effects were observed. Patients (67) healed without complications in from 3-17 wk. depending upon the severity of the disorder; the times given were to complete recovery in terms of the laboratory findings; 23 cases followed a protracted course; in 14 it became necessary to give adrenal corticoids also. No cure was achieved in 10 patients after 3 mo. of treatment; 7 could not be followed up, 1 case had a postnecrotic, cicatrized liver, and 2 had subchronic hepatitis. A review of the literature revealed that this record in treatment of hepatitis was equaled by some but not exceeded.

7563 RESULTS OF OBSERVATION ON A DISPENSARY LEVEL ON CHILDREN HAVING SUSTAINED EPIDEMIC HEPATITIS. (Rus.) Gol'zand, I. V. (Leningrad Inst. Res. In Pediatric Infectious Diseases, USSR). Vop. Okhr. Materin. Dets. 11(11):45-50, 1966.

A study was made on 472 children (1 yr. of observation, 472; 2 yr., 263; 3 yr., 135; 4 yr., 98; and 5 yr., 57 children) who had viral hepatitis up to 5 yr. previously (69.2% had a moderately severe form; 25.2% a mild form and 5.6% the anicteric form); 249 of them were treated during the acute phase of the disease with hormones and symptomatic therapy, 180 with symptomatic therapy alone, and 35 with chloroquine and symptomatic therapy. At release, hepatomegaly was found in 36.3%, and after 1-5 yr. in 29% of the patients. Hyperbilirubinemia (usually not exceeding 2 mg%) at release was found in 3.6%, and during the entire subsequent observation period it occurred in not more than 7.5% of the patients. A decrease of total protein with an increase in γ-globulins was found in the period of up to 12 mo. in 44% of the convalescents who had C-reactive protein during the acute phase of the disease; when the latter was absent the blood picture was normal in 80% of the cases. A decrease in pancreatic excretory function during the acute phase was observed in 95.5%, and the decrease remained in 40% even 1 yr. after the disease. C-reactive protein in the acute phase was present in 61%, and at day 25 of the disease positive tests were found in only 9% of the patients. In the convalescents a slightly positive test was noted in 15% of the cases in the period of up to 6 mo. Immunologic reaction in the acute period was positive in only 44.4%, while in convalescence in the period of up to 6 mo. this percentage increased to 79.5%, i.e., it corresponded to normal. On the fifteenth-twentieth days of the disease (which had a cyclic course) 72.5% had a positive reaction to total autoantibodies; this gradually decreased and was present in 6.4-7.0% after 2-4 yr. In the cyclic course of hepatitis the total autoantibodies were measured in 42.4-36.6% after 3-12 mo. of convalescence. Pancreatic autoantibodies were found in 12.5%-14.4% of convalescents for periods of up to 2 yr.; after 3-5 yr. they were found in 4.7% of the cases. Such antibodies were absent in healthy children. Exacerbation occurred most frequently during the first 3 mo. after release, and its frequency did not exceed 4.6%. At release, residual symptoms were found in 50% of the cases; after 1 yr., they were found in 37.4%; after 2 and 3 yr., in 26%; after 4 yr. in 34% and after 5 yr. in 35.2% of the convalescents. A normalization of biochemical tests and improvement in general condition before release were found in 49.1%; after 1 yr. in 62.6%, after 2- and 3 yr. in 74.0%, after 4 yr. in 66.8% and after 5 yr. in 64.8% of the patients. There was no correlation between the severity of the disease and the course of convalescence, or between the type of therapy used in the acute period of hepatitis and further characteristics of the convalescent period. The necessity of systemic observation of convalescents for more than 6 mo. is emphasized.

7564 SOME PROBLEMS OF TUNGSTEN METABOLISM IN EPIDEMIC HEPATITIS. (Rus.) Dontsov, G. I. (Sverdlovsk Med. Inst., USSR). Sovet. Med. 29(12):14-17, 1966.

The tungsten content (determined by the photocolorimetric rhodanide method) in blood, urine and feces of healthy individuals living in or near Sverdlovsk was 9.28 μg%, 440.18 μg% and 341.13 μg%, resp. In 190 patients (17-60 yr. old) with viral hepatitis of light or mild form (Group 1, 49 patients), moderately severe (Group 2, 90 patients) and severe forms (Group 3, 51 patients), there was a relationship between tungsten content of blood, urine and feces, and the severity and phase of the disease. At the peak of the disease, the content of tungsten in blood for Groups 1-3 was 41.6-88.5 μg%, while at release (clinical cure) it was 20.0 μg% to normal values. During pronounced clinical symptoms the urine tungsten content was decreased, especially in Group 3 (119.4 μg%); at the start of improvement it increased (Groups 1-3, 262.4-243.1 μg%) and at clinical cure it was normalized. Normalization of tungsten content in blood and urine is explained by the action of steroids and glucocorticocoids. The tungsten content of feces at the peak of the disease in Groups 1-3 was decreased and varied between 134.5-64.1 μg%; however, in clinical cure it increased and reached 161.8-225.9 μg%. These low values are explained by an accumulation of tungsten in bones, liver and other parenchymal organs. In 19 convalescents bile mixed with duodenal content contained an av. of 10.8 μg% of tungsten; gallbladder bile contained 59.0 μg% and hepatic bile 16.4 μg%. Patients received up to 600 μg of tungsten daily with their food. In viscera of patients with viral hepatitis the tungsten content was 1.5-3.0 times higher than in those of healthy persons (who had died in accidents).

7565 24-HOUR VARIATIONS OF UROBILIN IN THE URINE OF CHILDREN WITH EPIDEMIC HEPATITIS. (Rus.) Efimova, S. P. (2nd Moscow Med. Inst.). Vop. Okhr. Materin. Dets. 11(11): 50-52, 1966.

Daily urinary excretion of urobilin was studied in 74 children (2-15 yr. old); studies were made in 43 during the course of viral hepatitis (of mild, moderately-severe and atypical forms), in 25 at periods of 1-12 mo. after the illness and in 14 children without liver pathology (7 healthy normals, 3 with scarlet fever, and 4 with respirat diseases). In healthy normals and in those with scarlet fever, the urobilin level was low, showin 1 or 2 peaks which did not exceed 2 mg%. In all children with viral hepatitis, minimum urobilin was 1 mg% and the max. level was 40-80 mg%. Fluctuations decreased and peaks were lower after the acute phase of the disease ended; however, in only 50% did the urobilin level normalize after clinical symptoms had disappeared. Urobilin level was independent of age, severity of the disease o other liver functions. The urobilin curve was normalized from 18-40 or more days after onset of the disease. Pathological urobilin curves were preserved for a long time in all patients with bile tract complications. The daily urinary urobilin excretion was normal in 16 of 26 patients observed for 1-12 mo. after the illness; they also showed no clinical or biochemical symptoms of hepatic lesions. Urobilin curves were pathologica in 5 patients observed after 1 or more yr.; all had bile tract lesions, but no biochemical shifts. In 3 patients, pathological urobilin curves were accompanied by biochemical shifts, characteristic of the acute period of disease. One patient, observed 2 yr. after a mild course of the disease, complained of decreased appetitie and periodic vomiting; biochemical indices of the blood did not show an acute process, but urobilin curves were pathologic (with fluctuations of up to 12 mg%). Puncture biopsy revealed portal fibrosis and microdrip adiposis of the hepatic epithelium. Thus, the daily urobilin flucturation, reflecting functional liver conditions, can be used in combination with clinical and biochemical data for solving the problem of diagnosis and prognosis in viral hepatitis.

7566 EPIDEMIOLOGY OF HEPATITIS. (Por.) Da Silva, A. M. J. Med. (Porto) 60(1228):863-866, 1966.

A statistical analysis of the incidence of virus hepatitis and hepatitis acquired by inoculation, in Angola Province, Portuguese Africa, is supplemented by a review of differential diagnosis and prophylaxis. The incidence of virus hepatitis in 1958, 1959 and 1960 was 2.0, 8.0 and 6.0 per 100,000, resp.; data for 1961 were not available; comparable tabulations for 1962, 1963, 1964 and 1965 were 7.5, 4.25, 4.0 and 6.5 per 100,000, resp. Approx. 55% of all cases of hepatitis, including both origins, occurred in individuals between 15 and 44 yr. of age; in the 8 yr. represented by the above tabulations, a total of 33,660 days were lost from work for this reason by 1122 persons in the age-range indicated. Viral hepatitis was encountered much more frequently

:hildren 5-15 yr. of age; hepatitis acquired
inoculation, in adults aged 20-44 yr. The
mortality rate for viral hepatitis was
ox. constant, at 2%; that for hepatitis
ired by inoculation fluctuated between 6-12%.

7 CHROMATOGRAPHIC STUDIES OF URINARY
AMINO ACIDS IN CHILDREN SUFFERING
VIRAL HEPATITIS. (It.) Frangini, V. (U.
ence, Italy), C. Moggi and G. Poggini. Riv.
. Pediat. 77(6):320-327, 1966.

ompared to 30 healthy children, (6-12 yr.
, chromatographic studies of 24-hr. urine
les derived from 13 children with viral
titis (5-12 yr. old) and having been ill for
ore than a wk., showed very markedly in-
sed urinary excretion of leucine, tyrosine,
ionine and tryptophan; less markedly, but
l significantly, increased excretion of
onine, proline and histidine. Variations in
excretion of lysine and phenylalanine were
at a level of statistical significance.
nine was found only rarely.

REPORT OF AN EPIDEMIC OF VIRAL
HEPATITIS IN A RURAL COMMUNITY. (It.)
li, G. (Bolognini Hosp., Bergamo, Italy),
ichera and I. Mantovani. Epatologia 12(4):
705, 1966.

21 cases of hepatitis with jaundice occurred
8 families in one small village, 69 of 72
diate relatives of the patients were also
ected to study. Both SGOT and SGPT levels
significantly above normal in 42 of 69
of 42, aged less than 30 yr.; 14 of 42,
30-50 yr.), all of whom had symptoms very
lar to those of patients with manifest
dice. In almost all the nonjaundiced patients,
SGOT:SGPT ratio was inverted and BSP reten-
and MacLagan's tests were positive. Although
obulin levels were abnormal, they were
as low as those found in jaundiced patients.
jority of patients in both groups had re-
red, with essentially normal laboratory
ings, by the end of a 4 mo. observation
od.

BLOOD COAGULATION STUDIES IN THE COURSE
OF HEPATITIS WITH JAUNDICE. (It.)
ani, E. (Civil Hosp., Monza, Italy) and
. Dinelli. Epatologia 12(4):726-731, 1966.

hrombodensity test" is described, consisting
hotometric assays of variations in opacity
h occur in plasma samples before and after
addition of thromboplastin. Among patients
only slight parenchymal liver damage due to
titis with jaundice, a slight increase of
optical density was found; among those with
re damage, a marked diminution of max.
cal density. A very marked increase of max.
ity appeared to be associated with hyper-
inogenemia in the presence of a tumor.

7570 CHRONIC, ACTIVE HEPATITIS. (It.)
Bertoni, L. (Hosp. Inst. Verona, Italy).
Epatologia 12(4):662-665, 1966.

In 2 men with chronic, recurrent hepatitis (43 and 47 yr. old, resp.) intensive, prolonged treatment with corticosteroids (no details) reduced temperature and transaminase levels and decreased asthenia, without being able to prevent periodic recurrence of active episodes. Both were put on combined therapy with 6-mercaptopurine (100 mg/day for 5 days; then 50 mg/day for 10 days; then 25 mg/day for 15 days), plus prednisone (30 mg/day for 30 days), repeated 6 times with 1 mo. rest between courses. Both showed progressive improvement throughout the treatment period, accompanied by total regression of purpura, hepato- and splenomegaly, and (in 1 of 2) rheumatic distress. Neither had experienced recurrence at the time of report (interval not indicated).

7571 SEQUELAE OF VIRAL HEPATITIS. (It.)
Grasso, E. (Civil Hosp. S. Croce,
Cuneo, Italy), G. F. Ferro and G. Vacca. Minerva
Med. 58(9):258-260, 1967.

Follow-up studies were made of 90 patients (14-65 yr. old) 6 mo. or more after complete recovery from viral hepatitis. Some hepatomegaly was found in 75%, discoloration of the tongue in 88%, subclinical jaundice of the sclera in 65%. There was no consistent relationship between such clinical findings, subjective complaints and/or laboratory findings, which were entirely normal in only 12 of 90 cases (13%). Serum cholesterol was reduced in 31% of the group; prothrombin levels in 28%. Serum alkaline phosphatase was increased in 26% and total serum bilirubin in 16%. SGOT was increased in 11%; SGPT, in 3.5%; BSP retention, in 5.5%. It is concluded that the frequency and severity of sequelae of viral hepatitis need further study.

7572 SERUM ENZYME PATTERNS IN VIRAL
HEPATITIS AS AN INDICATION OF THE
INTRACELLULAR SITE OF DAMAGE TO THE LIVER CELL.
(It.) Pagliaro, L. (U. Palermo, Italy).
Epatologia 12(4):652-659, 1966.

During the first 2 wk. of illness from viral hepatitis, serum levels of the anionic fraction of SGOT (SGOT$_1$), sorbitol dehydrogenase, SGPT and phosphohexoiso-isomerase, all enzymes which originate in the unstructured fraction of cytoplasm, increased much more rapidly than did those of glutamic dehydrogenase, ornithine carbamyl transferase, or the cationic fraction of SGOT (SGOT$_2$), which originate in the mitochondria. The peak serum activity of these "cytoplasmic" enzymes was also reached somewhat earlier than that of the mitochondrial enzymes, so that the latter continued to rise after the former had begun to fall. Similar phenomena were not observed in patients with hepatoma or cirrhosis of the liver. It is concluded that the initial liver-cell damage in viral hepatitis is done to the cytoplasm and probably extends to the mitochondria only because of the intervention of a secondary, nonspecific mechanism of action.

7573 ANTIHEPATIC ANTIBODIES IN VIRAL HEPATITIS. (It.) Grassi, B. (U. Pisa, Italy), C. Loni, F. Ambrogi, G. Bellucci and A. Salvetti. *Epatologia* 12(3):521-526, 1966.

In the serum of healthy controls, antiliver antibodies could be demonstrated in 2 of 7 cases. They were also demonstrable in the serum of 5 of 6 patients with rheumatoid arthritis and in 1 patient, each, with scleroderma and pulmonary silicosis. In all instances the agglutination titer ranged from 1:2-1:4. Among patients with acute viral hepatitis, antiliver antibodies were demonstrable in the serum of 11 of 14, with agglutination titers ranging from 1:4-1:64; in direct proportion to the degree of dysproteinemia especially in terms of increased gamma-globulins. Following emergence from the acute phase of the disorder, these titers fell progressively over a period of 1-4 mo., prior to complete disappearance of the antibodies. In the serum of another group of patients, tested 30-120 days after the acute phase of the illness was over, antiliver antibodies were found in 5 of 9 cases, with agglutination titers ranging from 1:2-1:8. It is suggested that they may be produced as a defense against the products of necrosis and/or tissue inflammation.

7574 PROPOSED METHOD FOR OBVIATING THE DANGER OF POST-TRANSFUSION VIRAL HEPATITIS. (It.) Genovese, E. (U. Milan, Italy) and Y. Nakamura. *Epatologia* 12(3):555-560, 1966.

When Xenaldial (an antiviral agent derived from diphenyl; no additional details), 100 µg/ml, was added to mouse hepatitis virus EHF-120 in suspension in physiologic saline, human serum and human whole blood, the infectious titer was reduced to zero within 48, 72 and 120-336 hr., resp. A review of the literature appeared to confirm that admin. of 25-50 mg during an infusion of 250-500 ml blood or plasma would entail no undesirable side effects. It is therefore suggested that this technic might be used as prophylaxis against the transmission of hepatitis virus.

7575 SERUM BILIRUBIN FRACTIONS IN VIRAL HEPATITIS. (It.) Monteverde, A. (Maggiore della Carità Hosp., Novara, Italy). *Epatologia* 12(3):561-572, 1966.

Among 96 patients with viral hepatitis, total serum bilirubin tended to decrease with the course of the disorder, with median values of 9.67 mg% (range, 2.2-23.3) during the first wk., 8.15 mg% (range, 0.8-25.6) during the second, 5.53 mg (range, 0.0-21.7) during the third, 4.8 mg% (range, 0.0-16.6) during the fourth. Comparable tabulations for total dire bilirubin were: 7.6 mg% (range, 1.9-19.7), 6.6 mg% (range, 0.0-19.0), 4.4 mg% (range, 0.0 21.4) and 3.6 mg% (range, 0.0-15.5), resp. Fo indirect bilirubin, they were: 2.05 mg% (rang 0.1-13.0), 1.7 mg% (range, 0.1-7.6), 1.05 mg% (range, 0.0-6.3) and 0.7 mg% (range, 0.0-3.6), resp. For alcohol-soluble direct bilirubin, t were: 3.5 mg% (range, 0.3-8.3), 2.2 mg% (rang 0.0-7.8), 1.2 mg% (range, 0.0-7.7) and 0.65 mg% (range, 0.0-5.9), resp. For precipitable direct bilirubin, they were: 4.1 mg% (range, 1.0-12.9), 4.3 mg% (range, 0.0-14.0), 3.15 mg% (range, 0.0-11.2) and 3.0 mg% (range, 0.0-9.6) resp. Mean values for precipitable direct bilirubin expressed as a percentage of total direct bilirubin were 54%, 63%, 70% and 82%, resp.

7576 COMPLETE STUDY OF THE NATURAL EVOLUT OF HEPATIC LESIONS IN HUMAN, ACUTE VIRAL HEPATITIS. (It.) Naccarato, R. (U. Padua, Italy), O. Fameli, L. Okolicsanyi, G. Previato and L. A. Scuro. *G. Mal. Infett.* 18(8):539-550, 1966.

Conventional and electron microscopic studies were made of liver biopsy specimens derived from 24 patients with acute viral hepatitis (duration of illness not in excess of 20 days) and 19 with the same disorder in a subacute phase (after more than 3 wk. of illness). In t first group lesions were characterized by a marked reduction of cellular glycogen content, accompanied by the presence of large amounts of agranular endoplasmic reticulum and a significant increase in the number of ribosomes which tended to be either free or grouped into small clumps. The later stage of the disorder was characterized by swelling of the mitochondr and the presence of much-increased amounts of granular endoplasmic reticulum, phenomena which appeared to be associated with degenerative and necrotic cellular processes representing the final stage of morphologic change induced by viral hepatitis in the human.

7577 AMINO AND UREA NITROGEN IN THE BLOOD OF CHILDREN SUFFERING FROM VIRAL HEPATITIS. (It.) Frangini, V. (U. Florence, Italy), C. Moggi and G. Poggini. *Riv. Clin. Pediat.* 77(6):328-333, 1966.

Among 13 children (5-13 yr. old) suffering from viral hepatitis, serum levels of urea ranged from 16.07-32.14 mg%, based on a formula for converting serum urea nitrogen (range = 8.0-15.0 mg%) to urea. The range of the amounts of nitrogen contained in serum amino acids was calculated as 3.9-6.8 mg%. Although the mean levels indicated did not deviate from the normal range at a level of statistical significance, an overall tendency toward slight hyperaminoacidemi

a concomitant, slight diminution of serum
els of urea indicated during the period of
ve illness.

WIDESPREAD SEARCH FOR THE ETIOLOGIC
AGENT RESPONSIBLE FOR HUMAN VIRAL
ATITIS. (It.) Babudieri, B. (U. Padua,
y), E. Fiaschi, R. Naccarato, L. A. Scuro,
Papa and F. Tangucci. G. Mal. Infett. 18(8):
-570, 1966.

electron microscopic study of liver biopsy
cimens derived from patients with viral
atitis showed dilatation of the canaliculi
the endoplasmic reticulum, occasional cytolysis
swelling of the mitochondria, accompanied
fragmentation of their cristae. A marked
rease in the number of ribosomes was also
erved, as was the fact that many of these
positioned abnormally. There was also a
ificant increase of cellular RNA. Semi-
sparent, virus-like particles, surrounded
a simple membrane and measuring approx. 200
diameter were found in the cytoplasm of
epithelial and histiocytic liver cells from
ents examined between 9 and 33 days after
t of illness. Gamma-globulin preparations
ved from human convalescent serum and
ugated with fluorescein histiocyanate showed
ually identical areas of fluorescence. In
tic biopsy sections, antiviral γ-globulin
ugated with ferritin yielded images suggesting
the particles in question were identical
the hepatitis virus. At the time of report,
first efforts were being made to culture a
line containing the particles in question.

INVOLVEMENT OF THE PANCREAS IN THE
COURSE OF VIRAL HEPATITIS: STUDY OF
NINE-HEXOPEPTIDASE ACTIVITY. (It.) Nuti, M.
Rome) and C. Prantera. Arch. Ital. Sci. Med.
. 47(9-10):221-226, 1966.

m arginine-hexopeptidase activity was in-
sed in 40 of 60 patients with viral hepatitis.
0 of 40, serum levels peaked between 20 and
(normal for adults = 14-18 U); in 30 of 40,
een 31 and 52 U. Barely discernible increases
evidenced during the acute phase of the
rder, with further increases taking place
ually during the 2-3 wk. following, prior to
ual, spontaneous normalization. Serum levels
xcess of 30 U were invariably associated
dyspeptic syndrome, epigastric pain radiating
he left shoulder, hypersalivation or other
toms of pancreatic involvement. There appeared
e no statistically significant relationship
een the activity of the enzyme under study
that of amylase. It is concluded that viral
atitis would appear to be only one aspect of
sorder which also involves the duodenum and
larger organs associated with it.

IMMUNOGLOBULINS AND INTERFERON RESPONSES
IN INFECTIOUS AND TRANSFUSION ASSOCIATED
HEPATITIS. (E.) LoGrippo. G. A. (Henry Ford
Hosp., Deteroit, Mich.), H. Hayashi and N.
Sharpless. Henry Ford Hosp. Med. Bull. 15(1):
57-63, 1967.

Twenty patients with hepatitis (11 infectious, 9 associated with blood transfusion) were observed during the acute jaundice stage, and 1 was studied for 18 mo. starting 1 yr. after acute onset of hepatitis. Serum immunoglobulin (Ig), (IgA, IgM, IgG) levels and leukocyte interferon responses were compared with total proteins, electrophoretic mobility of serum proteins, SGOT, and bilirubin levels (total/direct). No correlation was observed between values in the γ-zone from electrophoresis and IgG values by immunochemical analysis. β-Zone patterns showed no evidence that IgM or IgA were abnormally high. It is recommended that immunochemistry, rather than electrophoresis, be used to quantitate immunoglobulins. In both types of hepatitis all the immunoglobulins were elevated during the jaundice stage. IgA and IgG values varied, but IgM values were consistently elevated. During recovery IgM values returned to normal and IgG values increased above normal, although 2 patients showed elevated IgM values at 18 and 30 mo., resp. Twenty patients showed "good" leukocyte interferon response.

7581 FURTHER STUDIES ON HAEMAGGLUTINATING AGENTS OBTAINED FROM ACUTE HEPATITIS SERA. (E.) Nagylucskay, S. (Univ. Med. Sch., Budapest, Hungary) and J. Angyal. Acta Microbiol. Acad. Sci. Hung. 13(3):189-192, 1966.

Sera were obtained from acute-phase blood samples from 99 hepatitis patients in the first 5-day period after initial symptoms of the disease; in addition, sera were obtained from 5 healthy donors, and convalescent sera from 13 patients with clinical diagnosis of infectious hepatitis and from 5 with serum hepatitis. In the allantoic fluid of chick embryos inoculated with acute-phase sera of viral hepatitis patients, a hemagglutinating agent developed similar to that contained in the serum; this confirmed previous findings. The agent could be maintained through numerous serial passages without loss of titer. Hepatitis convalescent sera mostly inhibited the hemagglutinating agent obtained either from acute-phase sera or in allantoic fluids. The sera of 2 rabbits immunized with an infectious hepatitis and serum hepatitis agent, resp., revealed only homologous inhibition. Preliminary neutralization tests in ovo appeared to be consistent with results of the hemagglutination inhibition tests. The hemagglutinating agents were highly resistant to heat; after being heated to 100° C for 20 min., the agents (50 of 52 allantoic fluids) still agglutinated tanninized human RBC, and the same treatment never prevented them from being maintenable in serial egg passages. Since hepatitis convalescent-phase sera often inhibited the hemagglutinating agents and this inhibition seemed to distinguish infectious hepatitis from serum hepatitis, there may be a possible specific reaction of the organism against the hemagglutinating agents.

7582 A GAS CHROMATOGRAPHIC STUDY OF FREE AND ESTERIFIED FATTY ACIDS IN THE PLASMA OF PATIENTS WITH INFANTILE VIRAL HEPATITIS.

(It.) Genova, R. (U. Modena, Italy) and V. Galli. Minerva Pediat. 18(26):1417-1424, 1966.

In 7 children with viral hepatitis (2 boys, 5 girls; 3.5-11 yr. old), pre- and post-treatment gas chromatographic studies showed a significant increase of total nonesterified fatty acids in the plasma at the time of diagnosis, with a median value of 813 μEq/liter (range, 500-1370 μEq/liter), which had returned to normal by the end of treatment in 5 of 7 cases; had continued to increase markedly in 2 of 7 (to 1000 and 2000 μEq/liter, resp.) despite clinical recovery and normalization of serum transaminase levels. This increase of nonesterified fatty acids was accompanied by a sufficient diminution of esterified fatty acids to maintain the serum level of total fatty acids within the normal range. Prior to treatment, the ratio of total saturated to total unsaturated fatty acids in the plasma was 37.58:61.16; after treatment, it was 37.36:63.54. Comparable ratios for nonesterified saturated against unsaturated fatty acids were 28.04:67.28 and 32.34:70.02, resp. As concerned percentage relationships of the individual fatty acids, esterified or nonesterified, no statistically significant differences were found between pre- and post-treatment analyses, with mono- and polyunsaturates both elevated above normal values at both times, suggesting that the liver's ability to synthesize phospholipids was preserved during the illness. The total duration of illness, and of the observation period, was 30-40 days. Corticosteroids were admin. to only 2 children, who received prednisone, 2 mg/kg/day x 7, repeated after an interval of 4 days.

7583 HEPATITIS IN INFANTS.

(Cz.) Raska, B. (Inst. Pediat. UDL, Prague). Cesk. Pediat. 21(10):885-891, 1966.

Epidemic hepatitis in infants often exhibits symptoms typical for intrahepatic obstruction jaundice. As these symptoms can be induced by several etiologic factors, laboratory tests have only a limited value in the differential diagnosis of viral hepatitis in infants. The serum test based on the shift of the ratio of albumins to globulins is especially useless, because of the very low level of γ-globulins 3-5 mo. after birth. Repeated duodenal sounds with admin. of $MgSO_4$ are valuable from both the diagnostic and therapeutic point of view and often break the functional blockage of the bile. To distinguish between transient and anatomical occlusions in infants, it is often necessary to carry out bioptic examination followed by postoperation cholangiography. The risk of exploratory leparotomy, applied under suitable conditions a at appropriate time, is low.

7584 NEW INFORMATION CONCERNING THE FUNCTIONAL DIAGNOSIS OF HEPATITIS IN CHILDREN.

(Cz.) Stroder, J. (Univ. Clin., Wurzburg, Germany). Cesk. Pediat. 21(10):865-8 1966.

The increased level of some enzymes and of bili in serum are useful critera for diagnosis of hepatitis in children during the acute phase of the disease. However, already 2-3 wk. after th appearance of hepatitis symptoms the level of these enzymes and of bilirubin returns usually normal values. Thus these tests cannot be used during the later stages of hepatitis for the determination of the severity of the disease an of the extent to which the liver of the childre was damaged. It was found that the levels of prothrombin, Factor VII, Factor IX, and Factor in sera of children were markedly reduced durin the first 2 wk. after the appearance of hepatiti symptoms. The impaired clotting of the blood correlated with the increased bilirubin content of the serum during this time interval. Later, the level of clotting factors became normal. However, during the recovery, i.e. 8-20 wk. aft the appearance of hepatitis symptoms, about 60% of children again had significantly decreased levels of prothrombin and of Factor VII in thei sera, although other serum tests were negative at that time. By special care during the recove period the incidence of recurrence, as indicate by decreased levels of clotting factors, could b substantially reduced. The response of children to the admin. of vitamin K is very variable. It may cause both an increase, as well as a further decrease, of the levels of clotting factors in the serum.

7585 REPEATED ISOLATIONS OF PREVIOUSLY UNKNOWN ADENOVIRUSES FROM PATIENTS WITH VIRAL HEPATITIS BY MEANS OF HISTOLOGICAL METHODS.

(Ger.) Köhler, H. (Koch Inst., Berlin J. Apodaca and D. Springer. Zbl. Bakt. (Orig.) 202(1):11-26, 1967.

Sera of patients with viral hepatitis were obtai from hospitals; samples were taken from these subjects for the period of 1 yr. until the sera proved to be sterile. Sera of patients free of hepatitis and with no history of the disease served as controls. The blood was used on the d it was taken or when necessary was refrigerated until the next day. The isolation of hitherto unknown viral strains was done in primary cell cultures of the cortex of the healthy hog kidney according to the method of Von Lembke and his coworkers; 5, 10, and 50 cultures were inoculate with a test serum while other cultures were inoculated with the control serum. Ten days aft inoculation the cultures were examined under the microscope for definite nuclear changes due to virus. The main changes consisted of increased e of the whole cell, with no apparent change the cytoplasm, but a more or less thick ophilic clumping in the nucleus and displace- t of the nucleoli to the nuclear periphery; gle or multiple large round eosinophilic lusions were also present in the nucleus; se were specific changes resulting from ection by adenovirus. Sterile control sera roduced into primary cultures of hog renal tex furnished proof that foreign viruses were present in the kidney preparation or in the ture medium. Increased virus conc. were ained from the supernatant medium of infected tures. Immune serum was obtained from rabbits . daily for 10 days with 1 ml of culture ernatant followed by a single booster shot k. before taking blood. Antisera to human noviruses 1-31 were tested. Serum taken m a hepatitis patient 13 days after onset of ndice, kept frozen at -20° C retained viable us after 156 days. Altogether 288 serum ples from clinical hepatitis patients were mined and 162 adenovirus isolations made. mination of the sera of 103 persons with arently clinically healthy livers resulted in y 10 virus isolations. Repeated examinations 62 patients with viral hepatitis from the inning of jaundice for 200 days showed the lowing: virus was isolated 6 times from 2 ients, 5 times from 6 patients, 4 times from atient, 3 times from 11 patients, 2 times from patients, and 1 time only from 19 patients. ing the first 20 days after jaundice 69.5% cases yielded positive virus isolations; ing the period 91-200 days virus was demon- ated in only 28.9%. None of the 40 viruses lated showed any serologic similarity to the known human adenoviruses; in no instance was possible to demonstrate the presence of tralizing antibodies even with homologous a. Experiments currently in progress have onstrated at least 2 diverse serotypes among isolates. Viruses isolated from the same ent were always serologically identical.

5 EXPERIENCES WITH THE RAPID COLOR TEST
FOR THE DETERMINATION OF SERUM ENZYMES
FIELD EXAMINATIONS DURING A HEPATITIS EPIDEMIC.
.) Wagenknecht, C. (Humboldt U., Berlin,
nany) and G. Anders. Deutsch. Gesundh.
3):589-592, 1967.

most sensitive indicator of disturbed hepatic ular metabolism is the serum enzyme activity. simultaneous determination of 2 serum enzymes and LDH which in the course of a case of l hepatitis showed max. values at different s, is broad enough to establish an early nosis and also to differentiate the disease ng its course; the color tests for these mes have been described by the authors in ious papers. The advantages of these tests a minimum of apparatus, an improvised ratory, a minimum of untrained personnel are the requirements; 1 person can do a large er of tests in a short time. The tests are so designed that the greatest sensitivity occurs when the enzyme conc. is only slightly elevated; the tests were calibrated by a spectrophotometer and are especially suited to field work in epidemiology. Altogether almost 10,000 enzyme determinations were made on 2820 persons; those suspected of contact with cases of hepatitis were tested twice/wk. for 3 wk. Among 2820 persons tested, 116 had definite cases of hepatitis endemica. Five patients were in early stages of jaundice; 3 had both enzymes elevated, 1 had SGOT only elevared and 1 LDH only elevated; 25 patients in early anicteric stages had this distribution (all enzymes listed having elevated conc.): 15 both, 10 SGOT. Becoming jaundiced (78): 8 both, 2 SGOT, and 68 LDH. Cases not healed (4), 2 both and 2 SGOT. Four had chronic liver disease, 2 both and 2 LDH. Of the 116, 30 were both, 15 SGOT and 71 LDH. Of those tested, 4.1% had the disease and of these 83% were anicteric.

7587 GALLSTONE FORMATION AND VIRUS HEPATITIS.
(Ger.) Demling, L. (U. Erlangen,
Germany), K. J. Bahn, H. Geidel and I. Bahn.
Deutsch. Med. Wschr. 92(14):652-654, 1967.

A study was made on a total of 6080 patients, 3016 men and 3064 women; of these 2024, 1063 men and 971 women, had undergone cholecystography; 1014 patients, 608 men and 406 women had suffered from viral hepatitis. A possible connection between hepatitis and cholelithiasis was sought with the aid of the Chi^2-test. With the exception of 3 cases, the minimal interval between hepatitis and cholecystography was 6 mo.; the av. time between the 2 was 12.9 yr. for the women and 14.9 yr. for the men. The frequency of cholecystography among patients with hepatitis was greater than among those without the disease. No correlation was found between the incidence of gallstones in men and a previous hepatitis. When the null-hypothesis was applied to the women, the probability of error was 0.01%. (For the entire group, the probability of error was less than 0.01%). This implies a negative correlation, between hepatitis and gallstone formation, i.e., those who formerly had hepatitis had significantly less lithiasis than those without hepatitis. This applied to all age groups.

7588 IN SPECIES SPECIFIC RESISTANCE
ALTERABLE BY ETHIONINE? I. INFECTION
EXPERIMENTS IN RATS WITH DUCKLING HEPATITIS VIRUS.
(E.) Lomniczi, B. (Vet. Med. Res. Inst., Acad.
Sci., Budapest). Z. Immun. Allergieforsch.
132(4):335-344, 1967.

Experimental rats were placed in 2 groups: those who received a normal semisynthetic diet; those who received a semisynthetic diet + 0.4% ethionine. Four serial transfers of duck hepatitis virus ($10^{6.3}$ LD_{50}/ml; in embryonated eggs) were made in rats pre-treated and not pretreated with ethionine. There was no difference in clinical signs and mortality between the ethionine-treated infected group and the ethionine-treated non-infected group (ethionine control) in 4 passages. In the second passage there was a slight increase in the incidence of mild jaundice in the ethionine-infected group. Four rats in the ethionine-infected group (total 55) and 3 in the ethionine-control group (35) died between days 3 and 8 after inoculation of intercurrent disease regularly occurring in ethionine rats (pneumonia due to Corynebacterium pseudotuberculosis, strangulation ileus). Histologic study of livers of 46 ethionine-infected rats killed from 3-9 days after inoculation, showed loss of definition of parenchymal columns, fatty degeneration or necrotization of parenchymal cells, swelling or pyknosis of cellular nuclei, accumulation of histiocyte-type cells, occasional appearance of very conspicuous nuclei, and sometimes periportal hemorrhage. No disease was observed in the normal-infected group. Pretreatment of rats with ethionine inhibited experimental transmission of duck hepatitis virus. Virus did not multiply in the ethionine rats, but could be demonstrated as active residual virus for at least 9 days whether rats were pretreated or not. Elimination of virus was slower in ethionine rats than in normals. Livers of ethionine rats showed uniform microscopic damage irrespective of whether they were infected or not.

7589 METABOLIC ASPECTS OF THE EVOLUTION OF HEPATOCELLULAR LESIONS INDUCED BY MHV-3. (It.) Coltorti, M. (U. Naples, Italy), A. Di Simone, G. Budillon, A. M. Barbieri and C. Del Vecchio-Blanco. Epatologia 12(3):426-437, 1966.

Mice infected with MHV-3 hepatitis virus, inoculated i.p., showed no significant changes of absolute values for total hepatic lysosomal enzymatic activity at any time during an observation period of 48 hr. after inoculation. However, a very marked increase in the activity of all free lysosomal fractions was demonstrated by the third hr., continuing through hr. 48, with a further rise following the onset of severe liver damage about hr. 24. RNA synthesis, which was not affected during the earlier stages of infection, also increased markedly toward the end of the observation period. Significant increases of serum levels of acid phosphatase, β-glucuronidase, cathepsin, arylsulfatase and ribonuclease appeared after 24 hr., preceded by an initial rise of serum arylsulfatase activity after 12 hr. and of serum ribonuclease and acid phosphatase activities after 18.

7607 ENZYMATIC ACTIVITY AND SWELLING IN SUSPENSIONS OF RAT LIVER MITOCHONDRIA BEFORE AND AFTER INCUBATION IN VITRO. (It.) Migneco, G. (U. Palermo, Italy), F. Giglio, S. Le Moli, L. Pagliaro and A. Notarbartolo. Fegato 12(3):341-351, 1966.

Homogenates were prepared from the livers of female Sprague-Dawley rats approx. 4 mo. old, previously fed a standard diet and weighing approx. 150 g. Prior to homogenization some of the livers were incubated for 3 hr. at 38°C in 10 ml CO_2-saturated Krebs-Ringer phosphate soln. containing 0.1% glucose. In all instances such incubation increased succinic dehydrogenase activity significantly, decreased ornithine carbamyl transferase activity significantly, induced a significant loss of soluble protein (as indicated by the ratio of glutamic dehydrogenase activity in mitochondrial protein to that found in supernatant protein) and decreased mitochondrial swelling progressively, as the pH of the incubation soln. was increased. Inasmuch as identical patterns of change were elicited in a previous study using homogenates of normal and cirrhotic human livers, it is concluded that the mitochondrial changes seen in cirrhotic human livers may be due to similar deprivation of O_2 and substrates.

7608 HEPATOPEXY USING TISSUE ADHESIVES AS A COMPLEMENTARY PROCEDURE TO END-TO-SIDE PORTACAVAL ANASTOMOSIS IN THE TREATMENT OF ASCITES (IMMEDIATE AND LONG-TERM RESULTS IN 33 OPERATED CASES). (Fr.) Belli, L. and D. Forti. J. Chir. (Paris) 92(6):589-606, 1966.

Hepatopexy using Eastman 910 acrylic adhesive was performed in 33 patients with cirrhosis and ascites; 31 also underwent end-to-side portacaval shunts. Esophageal varices were present in 20 cases and hemorrhage in 10. Nearly all of the 21 patients presenting with massive ascites also showed severe protein depletion, electrolyte imbalance, and liver function disturbances, and proved relatively resistant to other treatment; the other 12 patients had moderate, episodic ascites, with less profound liver function disturbances in 8 cases. The adhesive was applied to the entire surface of the liver at operation; subhepatic drainage was sometimes performed in the immediate postoperative period. Two patients (7% of the group) died of hemorrhage after 7-14 days; both had marked ascites and had proved refractory to diuretics. The other 31 patients were discharged in good condition 20-35 days postoperatively. A slight recurrence of ascites was noted in 3 patients (all initially presenting with massive ascites) after 10-15 days; all responded promptly to diuretics and transfusions. All 8 evaluable patients initially presenting with moderate ascites were alive without recurrence after 1-3 yr. In the 15 evaluable patients initially presenting with massive ascites, the mortality rate after 1 and 2 yr., was 15% and 30%, resp. None of these patients died of recurrent ascite the 2 deaths in the first 12 mo. were due to hepatic coma with jaundice, while the 4 deaths in the second yr. resulted from stomach cancer (1), hemorrhage from ruptured esophageal varice (1), hepatic coma (1) or undetermined causes (1 At the time of report, 9 of these patients were alive (6 after over 3 yr.); only 2 had presente recurrent ascites, easily controlled by diureti and protein replacement therapy. The general condition was good in all cases, although sever showed serious liver function disturbances and patients in this group had episodes of "porto-systemic" encephalopathy with edema.

7609 HEPATIC VASCULAR CHANGES IN HUMAN AND EXPERIMENTAL CIRRHOSIS. (E.) Mitra, S. K. (Roy. Free Hosp., London). J. Path. Bac 92(2):405-414, 1966.

Cirrhosis was induced in 60 rats by s.c. inj. o CCl_4 (0.1 ml/100 g body wt.) twice weekly for 18-56 wk. (54 survived). Biliary obstruction w induced by ligation and division of the common bile duct in 30 rats (13 survived). Cirrhotic (35) and obstructed livers (13) were inj. with India ink and 3% carmine-1% gelatin through different vessels; 2 vascular compartments were i at a time and fluids were introduced simultaneously. Livers were removed after ligation of vessels and fixed in 4% formaldehyde in sali for 3 days. At autopsy 5 human cirrhotic liver were removed and similarly inj. Vinylite-corro casts were made. Cirrhotic rats had all 3 possible types of shunts: hepatic artery-portal vein; portal vein-hepatic vein; hepatic artery-hepatic vein. Human livers had the first 2. Arterio-portal shunts exist in normal liver and dilate in cirrhosis due to arterial enlargement Other types possibly develop from persisting sinusoids in the fibrous septa. Livers obstructed for 6 wk. had no pathological shunts. Shunts may develop only after very prolonged obstruction, with onset of true nodular cirrhosis Hepatic, and also portal, veins in human livers were reduced in number and flattened and distor by regenerating nodules. Both venous trees wer similarly distorted in rats. Regenerating nodu were mainly supplied by portal venous branches, only rarely by arterial twigs, and their blood supply was less than that of normal parenchyma. Hepatic arteries were enlarged and increased in number in human livers. In the fibrous septa there were rich arterial plexuses which supply proliferated bile ducts and connective tissue. Such plexuses were also prominent in rats, seen mainly around the proliferated bile ducts, as the septa were not so broad.

7610 PORTAL BLOOD FLOW IN CIRRHOSIS OF THE LIVER. (E.) Moreno, A. H. (Lenox Hill Hosp., New York City), A. R. Burchell,

. Rousselot, W. F. Panke, S. F. Slafsky and
. Burke. J. Clin. Invest. 46(3):436-445, 1967.

ct measurements of flow and pressure and
(116) in the portal vein of 85 patients
cirrhosis (30 with associated ascites) showed
rked reduction in flow associated with an
st constant plateau of portal pressure. Lack
orrelation indicated the complex relation-
s of resistances in the splanchnic, collateral,
hepatic circuits determining the division of
available splanchnic flow between the portal
and collateral pathways. Subtraction of
ured portal flow from accepted estimates of
l hepatic blood flow in cirrhosis suggested
the hepatic artery contributes more than
of the blood passing through the cirrhotic
r. No retrograde portal flow was observed
ng preshunt measurements, but this was common
r side-to-side portacaval anastomosis. To
ain the plateau of portal pressure in con-
tion with increased outflow resistance pre-
bly associated with progress of disease, it
suggested that splanchnic flow in cirrhosis
educed by an augmented inflow resistance to
splanchnic chamber. End-to-end portacaval
tomosis reduced pressure to acceptable con-
levels, but did not return normal portal
. It is suggested that most of the splanchnic
d was flowing through the shunt and that this
to a high splanchnic resistance immediately
r the shunt. If this resistance was pre-
sly elevated, as is suggested by the portal
sure plateau, the mechanism responsible for
elevation was not stopped immediately after
shunt, and the true effect of the operation
planchnic flow may not be measurable at this
. Respiratory oscillations were a significant
onent of the portal flow in cirrhosis before
after portacaval anastomosis, limiting steady
e analysis of the circulatory derangement
rrhosis.

A STUDY OF SERUM ALKALINE RIBONUCLEASE
ACTIVITY IN THE COURSE OF CIRRHOSIS
HE LIVER. (It.) Doniselli, M. G. (U. Milan,
). Settimana Med. 54(11):591-594, 1966.

alkaline ribonuclease activity (expressed
he mean percentage of depolymerized ribo-
eic acid) was determined for 16 normal con-
, 31 patients with cirrhosis of the liver
without hepatic coma, 9 patients with cir-
s and hepatic coma (fatal in 4 of 9) and
cirrhotic groups combined, as follows:
, 31.3%, 31.9% and 31.4%, resp. It is
uded that serum alkaline ribonuclease
ity is increased in patients with cirrhosis
he liver, at a level of statistical sig-
cance, but that the degree of increase does
ppear to be correlated with the duration
llness, the degree of severity, the extent
undice, hepatomegaly, atrophy, alcoholism
revious hepatitis.

7612 TREATMENT OF PRIMARY BILIARY CIRRHOSIS WITH AZATHIOPRINE. (E.) Fischer, J. A. (Med. U., Zurich, Switzerland) and M. Schmid. Lancet 1(7487):421-424, 1967.

A 46-yr.-old woman with microscopically confirmed primary biliary cirrhosis with a focal distribution and without jaundice showed remission after treatment with azathioprine. At the time of initial diagnosis, a high level of nonspecific mitochondrial antibodies was noted along with a complement fixation titer in excess of 1/256. No antinuclear factors were detected. Upon readmission 1 mo. later treatment with azathioprine (100-200 mg/daily) was started, resulting in a marked decrease in liver size, reduction in splenomegaly, lowered serum alkaline phosphatase (to 21.0 Bodansky U) and elevation in serum bilirubin. The drug was discontinued after adverse hematologic effects and the liver again increased in size. Following recovery of RBC and WBC levels, treatment was resumed (50 mg/day) resulting in eventual wt. gain, disappearance in pruritis and less hepatic infiltration as shown by small-needle biopsy. In a 52-yr.-old male with frank cirrhosis, marked jaundice and severe pruritis, treatment with azathioprine (300 mg/day for 11 days and then 200 mg/day for approx. 5-6 mo.) reduced the pruritis and the patient manifested some subjective improvement. The liver size did not show any reduction during treatment and the spleen remained palpable. Slight periorbital xanthelasma remained unchanged. There was a decrease in both serum alkaline phosphatase and bilirubin levels. Increased application of azathioprine in the treatment of primary biliary cirrhosis is recommended.

7613 ARTICULAR MANIFESTATIONS OF PRIMARY BILIARY CIRRHOSIS. (Fr.) Hawthorn, E. and M. Magnan. Marseille Med. 104(2):125-133, 1967.

Two cases of "biliary rheumatism" are presented in whom inflammatory arthropathies appeared 2 yr. (1st case) and simultaneously (2nd case) with the symptoms of primary biliary cirrhosis. These rheumatic symptoms differ from those of chronic rheumatism in that they are less severe (responding well to treatment with aspirin), less evident physically, nonsymmetrical in occurrence, and have a more irregular evolution. In the first case, the arthropathy of the knee and shoulders responded to 4 g/day of aspirin until the patient returned 2 yr. later with complaints of abdominal pain, and diarrhea. Jaundice was evident. The rheumatism had developed further, affecting the finger joints (Hippocratic fingers) and spinal cord. Hepatic biopsy led to the diagnosis of Waldenstrom's disease and the patient was treated with 30 mg of delta-cortisone and 1 g of Penimepicycline each day. Improvement was rapid but 2 mo. later primary biliary cirrhosis was frankly evident. Arginine and vitamin D were added to the treatment. With the second patient the primary biliary cirrhosis was evident along with the transient arthralgia and minor decalcification. Movement of the wrists was painful and this patient also presented Hippocratic fingers. Treatment included 30 mg of delta-cortisone and 1 g of chlortetracycline. In conclusion, it is recommended that a biliary rheumatism be considered in patients who present with inflammatory arthralgias and Hippocratic fingers.

7614 STUDY OF THE URINARY ELIMINATION OF POTASSIUM AND SODIUM IN THE CIRRHOTIC WITH ASCITES.

(Fr.) Vivien, P. (Ther. Clin., Rennes, France), J. Gastard, J. Loussouarn, P. Saint-Drenant and P. Cousin. Therapie 22(1):177-189, 1967.

Determinations made from 30 cases of alcoholic cirrhosis demonstrated that the K/Na ratio in the urine is higher with ascitic cirrhosis than that found normally (control av. ratio was 0.36). The K/Na ratio was between 1 and 15 for 23 patients, with ratios between 1 and 4 for 16 of the 23; in only 3 of the 30 cases was the ratio less than 0.5. In total, 10 died; the percentage of deaths increased as the ratio increased. This held true in both the untreated as well as the 20 patients treated with diuretics (either spironolactones or Triamterene) or the 12 who received 30-40 mg of delta-cortisone. Of 12 patients who received 400 mg of aldactone alone and the 5 who received this in association with corticosteroids, 7 died. The K/Na ratio served as an indicator of the treatment efficacy; the successful cases were those wherein the ratio decreased to 0.5-0.8 with a progressive wt. loss. The corticosteroid served to lower this ratio more and lessened the post-therapeutic rebound. Of those who received only corticosteroids, half showed definite or temporary relief. The success of punctures was questionable. Even though an increase in K/Na ratio is not specific for cirrhosis but indicates rather, a defense mechanism against a loss of plasma, it serves well both in prognosis and evaluation of diuretic treatment with cirrhosis.

7615 EFFECTS OF OCTANOIC ACID ON SERUM-LEVELS OF FREE FATTY ACIDS, INSULIN, AND GLUCOSE IN PATIENTS WITH CIRRHOSIS AND IN HEALTHY VOLUNTEERS.

(E.) Linscheer, W. G. (Tufts U. Sch. Med., Boston, Mass.), D. Slone and T. C. Chalmers. Lancet 1(7490):593-597, 1967.

The effects of intraduodenal infusions of glucose and octanoic acid on the serum levels of glucose, insulin and free fatty acids were determined in 4 healthy male volunteers (20-35 yr. old) and in 5 patients (4 male, 1 female; 44-67 yr. old) with cirrhosis. Two glucose infusions were given to all subjects, and octanoic acid was added to 1 of 2 infusions in random order; octanoic acid alone was infused in 2 cirrhotics. Both test soln. contained glucose (138.9 mg/ml), sodium taurocholate (20 mg/ml) and NaCl (8.5 mg/ml) in
water; 1 soln. also contained octanoic acid
(10 mg/ml). Serum glucose, octanoic acid, insu
and total free fatty acids were determined befo
during and after infusion. Serum insulin level
rose in both groups during glucose infusions, b
the rise was significantly greater when octanoi
acid was added; this effect did not appear to b
mediated by the serum glucose because addition
of octanoic acid did not affect this level.
Serum free fatty acids fell in both groups but
inclusion of octanoic acid had no effect on the
rate of fall of serum free fatty acids. In bot
groups there were no measurable levels of octan
acid detected during glucose infusion alone, bu
measurable levels of the latter agent were dete
able within 10 min. of infusion when it was add
to the glucose infusion. After discontinuation
of infusion, a return to fasting levels of octa
acid was delayed as compared to the volunteers.
In 2 cirrhotic patients infused with octanoic
acid alone, no change in glucose or insulin con
was detected throughout the infusion; serum
octanoic acid levels were observed that were
identical with those of cirrhotics given an infusion containing octanoic acid and glucose.
Cirrhotics showed significantly higher levels
of serum insulin, glucose and free fatty acids;
however, the 2 groups were not age-matched and
conclusions were made, since glucose tolerance
decreases in older age groups.

7616 SOME ASPECTS OF CATECHOLAMINE METABO IN CIRRHOSIS OF THE LIVER.

(It.) Bannò, S. (U. Pavia, Italy) and A. Buzzetti.
Policlinico [Med.] 73(6):376-386, 1966.

Following a review of divergent experimental ar
clinical reports concerning serum and urinary
conc. of catecholamines in the presence of cirrhosis of the liver, a report is made of a stuc
of the 24-hr. urinary excretion of epinephrine
norepinephrine and vanilmandelic acid in 14
decompensated cirrhotic patients, all with asc
and all with diagnosis verified by biopsy. Nor
was receiving therapy which could influence the
results of the study and all were on diets free
of alcohol, tea, coffee and sweets. As compare
with 12 normal subjects of similar age, receiv
the same type of diet and receiving no medicat
of any kind during the observation period, no
statistically significant differences were four
It is suggested that compensatory mechanisms o
degradation, especially those involving ortho-
methylation and subsequent conjugation, may be
able to compensate even a markedly diminished
ability of the liver to metabolize these substances.

7617 CHANGES OF IMMUNITY IN PATIENTS WITH CIRRHOSIS OF THE LIVER, BEFORE AND AFTER TREATMENT WITH TESTOSTERONE PROPIONATE.

(It.) Cicchini, T. (U. Rome), M. Cao-Pinna an
G. Giannini. G. Mal. Infett. 18(1):43-47, 196

When blood derived from 16 patients with cirrh

ne liver (11 men, 5 women; 42-68 yr. old)
tested against *Staphylococcus aureus* before
after 60 days of treatment with testosterone
ionate, the mean phagocytic index rose from
-1.02 (ranges, 0.60-1.10 and 0.75-1.20,
), the mean opsonic index rose from 0.52-
(ranges, 0.30-0.69 and 0.55-0.80, resp.),
the mean number of colonies of *S. aureus*
loped per cm^2 on agar fell from 388-327
ges, 210-510 and 188-415, resp.), with in-
dual differences ranging from -95 to -22
n, -59). It is concluded that treatment
rrhosis of the liver with testosterone
onate resulted in significant improvement of
body defenses and natural immunity against
erial invasion.

THE ANTIGLOBULIN TEST WITH TANNED RED
CELLS IN PATIENTS WITH CIRRHOSIS OF
LIVER. (E.) Hoenig, V. (Charles U., Prague)
J. Hoenigová. *Z. Immun. Allergieforsch.*
3):233-239, 1967.

ed human RBC, treated with sera from 16
ents with hepatic cirrhosis and sera from
ormal patients, were exposed to antiglobulin
n or to antiserum to non-γ-globulin. Agglu-
tion was similar in the normal and cirrhotic
with the total antiglobulin serum. With
anti-non-γ-globulin serum, agglutination was
pronounced in the cirrhotic group. This
that serum globulins from both groups are
to tanned RBC and that binding of serum
γ-globulin is more pronounced with sera of
hotic patients than with normal sera. It is
ested that the activity of a factor inhibiting
binding of serum non-γ-globulin to tanned RBC
educed in cirrhotic sera as compared with
al. It is believed that these results have a
icochemical, rather than an immunological, basis.

SERUM 5-RIBONUCLEOTIDE PHOSPHOHYDROLASE
ACTIVITY IN LIVER CIRRHOSIS. (E.)
i, G. C. (U. Milan, Italy), A. Rezzonico and
ervasini. *Enzym. Biol. Clin.* (*Basel*) 8(1):
, 1967.

serum levels of activity of 5-ribonucleotide
hohydrolase had been found in patients with
ases of the hepatobiliary tract, including
ic cirrhosis, although levels were normal
hepatic coma. Enzyme levels in early hepatic
osis (11 patients), advanced cirrhosis (18)
epatic coma (6) were studied. There were
rmals. Diagnosis of cirrhosis was con-
ed by needle biopsy and liver function tests.
alkaline phosphatase was inhibited by
enediamine tetraacetic acid. Mean levels of
e activity were 0.43 in normals; 1.79 with
cirrhosis; 1.09 with advanced cirrhosis;
with hepatic coma. The reduction in levels
vanced cirrhosis and hepatic coma may be
o failure of synthesis within the liver,
occurs in advanced stages of cirrhosis.
was a significant correlation between re-
on of enzyme activity and low levels of
albumin, but no correlation with changes
rothrombin, cholinesterase, α_2-globulins, or
alkaline phosphatase. Reduction in enzymatic activity may be related to low conc. of substrates of the ATP system. Since this enzyme is localized in nuclei and the microsomes, the results may indicate damage to these organelles in hepatic cirrhosis and hepatic coma.

7620 HEMODYNAMICS IN THE CIRRHOTIC PATIENT DURING PARACENTESIS. (E.) Knauer, C. M. (Santa Clara County Hosp. & Med. Ctr., San Jose, Calif.) and H. M. Lowe. *New Eng. J. Med.* 276(9):491-496, 1967.

The effect of measured paracentesis upon hepatic vein wedge pressure, inferior vena cava pressure, i.p. pressure and cardiac output was investigated in 10 patients (5 male and 5 female) with liver cirrhosis and tense ascites. Observations included liver function tests, measurement of serum electrolytes, blood vol. determinations using ^{51}Cr-tagged RBC, ascitic vol. measurements by the BSP dilution technic. Cardiac output increased significantly (115-117% of control value) following removal of 250 ml of fluid and was maintained through 1000 ml. A trend to lowered cardiac output was observed in 7 patients who had more than 1000 ml withdrawn. Two of the 3 patients with ascitic vol. representing 20-25% of total body wt. showed an initial increase in cardiac output, only after removal of 1000 ml of fluid. Increased stroke vol. (115-119%) paralleled changes in cardiac output, and both are probably the result of increased venous return. Increase in peripheral resistance was observed early in paracentesis and remained uniform through removal of 1000 ml of fluid. Decompression resulted in a progressive and fairly uniform decrease in intra-abdominal pressure to 83% of base level after removal of 1000 ml of fluid. Such a decrease is thought to relieve obstruction of the inferior vena cava at the diaphragm. Five of 8 patients showed lowered hepatic wedge pressure (78% at 100 ml; 66% at 750-1000 ml) during paracentesis while the remaining 3 patients showed increased pressures which paralleled changes in cardiac output and were associated with only a 5% decrease in intra-abdominal pressure. Absolute vena cava pressures (8-17.5 mm) correlated with individual ascitic fluid vol. and abdominal tenseness.

7621 THE VALUE OF LYMPHOGRAPHY IN THE PORTAL HYPERTENSION OF LIVER CIRRHOSIS. (Ger.) Schreiber, H. W. (Marien Hosp., Hamburg, Germany), W. Koch and K. Diederich. *Langenbeck. Arch. Klin. Chir.* 317(2):124-139, 1967.

Lymphograms were obtained from those with healthy livers and those with liver cirrhosis, some having portal hypertension with and without ascites, before and after portacaval anastomoses, in order to gain information about (1) possible untoward side reactions of the technic; (2) the filling and form of the thoracic duct; (3) the filling and form of the retroperitoneal lymph vessels; and (4) the comparison of lymphographic and clinical findings. A 7 ml vol. of contrast medium made visible with 11% aqueous patent-blue soln. was pumped into the lymph vessels of the dorsal surfaces of both feet. The filling of the thoracic duct with contrast medium took place after the inj. as shown on X-ray films taken 6-24 hr. later. With proper timing and the control of X-ray intensity the delayed filling phases were recorded. The complete lymphographic record of a patient required 3 days including ancillary data comprising: (1) blood pressure, (2) electrocardiogram, (3) vital capacity, (4) sedimentation rate, (5) differential blood cell counts, (6) liver and kidney function tests. Subjective and objective disturbances were not encountered during the taking of lymphograms. In patients with portal hypertension the enlargement of the thoracic duct was a facultative symptom and result of an increased vol. and compensating flow of intra- and extrahepatic lymph. In patients with liver cirrhosis and ascites, a deficient flow of lymph in the thoracic duct was observed. From such observations and agreement between lymphographic and clinical findings, new therapeutic technics such as the cannulation and broad anastomosis of the thoracic duct with the subclavian and jugular veins, or the vena cava become possible for the prevention of hemorrhage from varices.

7622 THROMBOCYTOPENIA AND LIVER CIRRHOSIS. (Ger.) Frick, W. (Neumunster Hosp., Germany). Schweiz. Med. Wschr. 97(13):407-413, 1967

In a group of 130 cases of liver cirrhosis of different etiologies, an effort was made to correlate (1) thrombocyte count (more than 150,000/m^3 in 54 cases, 41.53%; between 100,000 and 150,000 in 14 patients, 10.77%; and less than 100,000 in 62, 47.70%; 58.47% with thrombopenia, all with less than 150,000/m^3) with other factors; (2) determination of total serum cholesterol and cholesterol esters, (3) serum bilirubin, (4) paper electrophoresis, (5) Takata reaction, (6) thymol turbidity test, (7) Weltmann coagulation band, (8) serum alkaline phosphatase, (9) serum levels of transaminases, (10) serum iron conc., (11) BSP test, (12) thromboplastin time, (13) bilirubin, urobilinogen and urobilin in urine, and urinary galactose test in some, (14) determination of size of spleen (chiefly by palpation and percussion) in some cases by X-ray. Diagnosis of liver cirrhosis was on the basis of laboratory tests and in 33 cases by biopsy. Unfortunately, although thrombocyte counts were made in 130 cases, measurement of the spleen was done in only 36 cases, WBC (not listed as a test parameter) in 15, and hemoglobin conc. (also not listed) in 58 cases. Some factors such as 24 hr. urinary excretion of estrogen in 8 cases, not mentioned elsewhere, are compared to the thrombocyte counts. A graph in the results shows the thrombocyte count plotted against the size of the spleen, expressed in g, of 33 autopsy cases not mentioned elsewhere. No relationship was found between platelet count and size of the spleen. The pathogenesis of thrombocytopenia in liver cirrhosis is obscure. The present findings rule out the existence of a hypersple
syndrome. The correlation between specific li
function tests and platelet count lead to the conclusion that liver damage is the primary ca
of thrombocytopenia. A disorder of maturation in the thrombopoietic system is unlikely; rath
it is felt that under the influence of the dam
liver the platelets are either formed abnormal
or damaged in the periphery. Relationships we
found between prothrombin time, BSP retention, serum albumins, and platelet count: the more pathologic the tests, the lower the platelet count. It is assumed that liver damage is the cause of the thrombocytopenia. As has been seen from the relationship between the individ
function tests and platelet count, the latter tends to fall as liver damage increases. Plat
count may, therefore, be used as a criterion for the evaluation of the severity of liver ci
rhosis.

7623 THE DIAGNOSTIC VALUE OF THE ELECTROENCEPHALOGRAM IN HEPATOPORTAL ENCEPHALOPATHY. A COMBINED CLINICAL AND STATISTICAL CONTRIBUTION TO THE PROBLEM OF NEUROLOGIC AND PSYCHOLOGIC CHANGES IN LIVER CIRRHOSIS AND PORTACAVAL ANASTOMOSIS. (Ger.) Penin, H. (Friedrich Wilhelm U., Bonn, Germany). Fortsc
Neurol. Psychiat. 35(4):173-234, 1967.

The diagnostic value of the electroencephalogr
(EEG) in the practical determination of hepatoportal encephalopathy is assayed in this paper on the basis of an exhaustive study of 256 patients with chronic liver cirrhosis and general
portal hypertension. Included is a history of the psychiatric study of encephalopathies cause
by portosystemic shunts, and the recent use (i
the last 20 yr.) of the EEG in this field. Th
possible physiologic and chemical causes of the
encephalopathies, their clinical symptomatolog
and neuropathology are considered as well as o
pertinent subjects such as the surgery of port
hypertension. The magnitude of EEG waves and t
forms in normal and psychopathologic conditions
are outlined. The data from the author's 256 patients have been correlated and analyzed in
every possible way. Of these 256 patients, 14
were not operated upon, including 10 with deco
pensated livers, 59 with varices without bleed
and 73 with bleeding varices; 114 patients had undergone operations and had direct portacaval anastomoses. These larger unoperated and opera
groups were subdivided into 4 groups each on t
basis of compensated and uncompensated cirrhos
time of shunt operation, etc. Simple and typi
values result from the comparison of encephalo
determined clinically (C) and by means of the
in these 8 subgroups: (1) 13% C, 2% EEG; (2) 2
18% EEG; (3) 41% C, 25% EEG; (4) 29%, C, 11% EE
(5) 29% C, 9% EEG; (6) 38% C, 7% EEG; (7) 32% C
8% EEG; (8) 30% C, 3% EEG. Three times as many
patients with encephalopathies were detected clinically as were by the EEG. Neurohistologic

minations disclosed no neural changes which
ld be correlated with the changes observed
the EEG of some patients, nor could histo-
hological liver findings be correlated with
encephalopathies.

7635 ARTERIAL CHANGES IN GANGRENE OF THE GALLBLADDER. (E.) Hargrove, T. K. (Harper Hosp., Deteroit, Mich.) and J. R. McDonald. Harper Hosp. Bull. 25(3):125-129, 1967.

A study was made of gangrene of the gallbladder (24 female, 21 male; 30-83 yr. old) who had undergone cholecystectomy between 1959-1966. Presenting signs included low grade fever (96%), WBC up to 15,000/ml (70%), acute pain (71%), a history of diabetes mellitus or arteriosclerotic heart disease (28%), and gallstones (90%). Original sections were stained with Verhoeff's elastic stain and a Van Gieson counterstain to delineate connective tissue, muscle and elastic lamina. Cross sections of several arteries in adventitial layer of wall were measured in each, using an ocular micrometer, and the av. ratio of thickness of arterial wall/lumen diameter was calculated as 0.5 X (external diameter - internal diameter)/internal diameter. Gross appearance of gangrenous gallbladder varied considerably. In the healing stage the wall became thick and fibrotic, with most severe fibrosis external to the mucosal coat. Mucosal necrosis, inflammation and hemorrhage were found in all specimens. Necrosis was transmural in 30% and limited to mucosa and muscularis in the rest. Gangrene was focal in 48%. Some thrombosed arteries were present in 34%. Of 81 perimuscular arteries measured, 54 showed concentric thickening, 27 eccentric. Thickening was limited to the intima, and the internal elastic membrane was intact. Av. ratio was 2.04 (range 0.5-16.0), whereas the generally accepted ratio in systemic arteries in 0.5. It is suggested that the primary lesion in the pathogenesis of gangrenous cholecystitis is arteriosclerotic thickening of the intima of gallbladder arteries. Although present in 90% of the cases, gallstones do not appear to be necessary for development of gangrene of the gallbladder.

7636 SURGICAL TIMING IN BILIARY TRACT DISEASE. (E.) Bruce, T. A. (U. British Columbia, Vancouver, Canada) and R. C. Harrison. Canad. Med. Ass. J. 96(18):1252-1257, 1967.

In a 4-yr. study of 991 cases of biliary tract disease, an elective operative mortality of 0.6% was observed (0.5% below age 65, 1.6% above), while that for acute cholecystitis was 4.4%. In 21 of 28 patients with acute cholecystitis, symptoms and signs subsided within 48 hr. of conservative management. On this basis, a 2-day trial of conservative management with gastric suction is suggested, with operation only for those not showing definite improvement. Operation is suggested for those with cholelithiasis with the view of reducing the risk of acute cholecystitis and of the high incidence of carcinoma accompanying cholelithiasis. Surgery did not always bring relief of "cholecystic indigestion," but a removal of the gallbladder and stones was often accompanied by relief from recurrent attacks of colic, and elimination of risks associated with acute cholecystitis, pancreatitis, ascending cholangitis, destructive jaundice and carcinoma of the bladder. Patients with a ruptured gallbladder should have minimal emergency operative treatment.

·7637 "SOLITARY DILATATION" OF THE BILIARY TRACT AS A PRINCIPAL FACTOR IN THE POST-CHOLECYSTECTOMY SYNDROME. (Fr.) Mallet-Guy, P. (Fac. Med., Lyon, France) and M. Gignoux. Lyon Chir. 63(1):45-72, 1967.

The post-cholecystectomy syndrome was noted in 492 of 6000 patients; solitary dilatation of the common bile duct was noted in 25 (5%) of this group. Recurrent symptoms developed within 1 yr in 10 cases, after 1-5 yr. in 11 cases, and afte 9-17 yr. in 3 cases; they tended to reproduce the symptoms of the initial episode. None of th patients responded to drug or hydromineral treatment. In 10 patients, dilatation of the common bile duct was observed at the time of cholecystectomy; the other 15 patients had been treated elsewhere and were observed by the authors only when recurrent symptoms developed. In the latte group, hypotonia of the sphincter of Oddi was noted in 9 cases; in the other 6 patients the sphincter was functionally normal. Right splanchnicectomy was performed in 8 patients; choledochoduodenostomy was indicated in the presence of marked dilatation of the sphincter o Oddi. Of the 14 operated patients followed up for 1 yr. or more (max. 10 yr.), 10 showed excellent responses; 1 patient showed an excelle response after repeat surgery to eliminate the anastomosis, 2 showed good responses, and 1 show a moderate response. No therapeutic failures we noted. This procedure is recommended to prevent the post-cholecystectomy syndrome.

7638 SYNDROME RESULTING FROM PARTIAL CHOLECYSTECTOMY. CLINICAL CONTRIBUTI (It.) Gatti, G. (Civil Hosp., Ivrea, Italy). Gazz. Int. Med. Chir. 71(17):1497-1513, 1966.

A review of the etiology, pathology and treatmen of post-cholecystectomy syndromes is complemente by report of 4 patients (1 man, 3 women; aged 38-52) who underwent partial cholecystectomy for chronic (3 of 4) or acute (1 of 4) cholecystitis and calculi. The patients returned to treatment 3-9 yr. later, after developing a syndrome consi ing of attacks of incapacitating pain, severe epigastric distress and dyspepsia. Pain could be precipitated in all cases by ingestion of fat in any form; 2 of 4 had also developed recurrent fever; 1 of 4 had transient attacks of jaundice. The biliary stump could be visualized in 3 of 4 and proved to be encysted and ectasic in all 3. Chronic pancreatitis and papillitis, without apparent involvement of the terminal segment of

e choledochus, had also developed in 1 of 4
o underwent papillostomy at the time of reinter-
ntion. The biliary stump was removed in
tirety in all patients, all of whom made un-
entful recoveries and were completely symptom-
ee at the time of follow-up, 6 mo. later. Also
ported is the case of a 49-yr.-old man in whom
newhat similar, but not incapacitating, symptoms
veloped, 6 yr. after partial cholecystectomy
r chronic cholecystitis and cholelithiasis, and
o recovered satisfactorily in response to diet
d symptomatic treatment alone.

39 CLINICAL SIGNIFICANCE OF THE AMPUTATION
NEUROMA AND LENGTH OF THE CYSTIC DUCT
MNANT. (E.) Berge, T. (U. Lund, Sweden) and
Haeger. Acta Chir. Scand. 133(1):55-60, 1967.

e cystic duct remnant in 40 cholecystectomized
ients (25 men, 15 women; 46-82 yr.) was measured
d examined histologically at autopsy. The
gth was measured with a catheter in its lumen.
e duct was then sectioned into 3-4 mm segments
ch were examined in relation to the degree of
rosis, tendency to nerve proliferation, and
mation of neuroma. The case histories were
died independently of knowledge of histologic
dings. Patients were classified into 4 groups:
never any postoperative abdominal symptoms;
symptoms which might have derived from the
iary tract; 3) symptoms fairly definitely
ginated in the biliary tract; 4) symptoms in
likelihood originated in the biliary tract,
aracteristic postcholecystectomy syndrome."
27 patients asymptomatic after operation, there
e 12, 5, 7, and 3 in Groups 1-4, resp. The
gth of the cystic duct was less than 1 cm in
1-2 cm in 9; 2-3 cm in 6; 3-4 cm in 5; 5-6 cm
1. Histological findings ranged from slight
rosis through more or less marked proliferation
nerves to classical amputation neuroma. Two
t remnants were wholly without demonstrable
tological changes, the rest having fibrosis of
ying degree. Distinct amputation neuroma was
erved in 11. In 6, such marked proliferation
nerves was seen as to be rated as a tendency
ard neuroma formation. There was no correla-
n between the length of duct remnant and
urrence of postoperative symptoms attributable
the biliary tract. There was also no
tistically significant difference in frequency
patients who were asymptomatic postoperatively
in those in whom symptoms probably attributable
the biliary tract were found. Caution should
used in suggesting that a neuroma, when found,
a long cystic duct remnant is in itself re-
nsible for the postcholecystectomy syndrome.

0 REACTIVE PROLIFERATION OF INTRAHEPATIC
BILIARY PATHWAYS. (EFFECTS OF OCCLUSION
OF SUBSEQUENT BILIARY RECANALIZATION.) (It.)
tiglioni, G. C. (U. Sassari, Italy). Gazz.
. Med. Chir. 72(4):277-298, 1967.

rats weighing 230 g at the start of the experiment, induction of cholestasis by ligation and section of the common bile duct resulted in marked dilatation and intense, progressive proliferation of intrahepatic biliary pathways, accompanied by degenerative changes in the liver parenchyma; a slowing in gain in body wt., as compared to controls; progressive increase in the relative wt. of the liver; marked, progressive increase of serum levels of cholesterol and total bilirubin; and portal hypertension. Subsequent resolution of the occlusion, after 1-51 days, by means of a cannula inserted into the dilated remainder of the choledochus, resulted in rapid, progressive reversal of all these changes, accompanied by atrophy of the neoformations and restoration of normal hepatic lobar architecture. However, the degree of normalization which could be achieved appeared to be inversely proportional to the duration of cholestasis, with permanent residual damage evidenced in animals in which the occlusion had been maintained for more than 21 days. The mortality rate for the second intervention also increased abruptly, rising from 17.3% when cholestasis had been maintained for 14 days, to 66.6% when it had been maintained for 21 days or more. This increase, in turn, was accompanied by a comparable reduction of subsequent survival times.

7641 FUNCTIONAL AND MORPHOLOGIC STUDY OF THE GALLBLADDER IN PATIENTS OPERATED FOR GASTRODUODENAL ULCER. (It.) Sarti, G. (U. Rome), L. Saracca, M. Ermini and N. Basso. Gazz. Int. Med. Chir. 72(1):5-23, 1967.

Cholecystography and X-ray studies of the biliary passages were performed in 5 groups of patients after surgery consisting of gastric resection plus gastrojejunostomy, gastric resection plus gastroduodenostomy, selective vagotomy, selective vagotomy plus pyloroplasty, or selective vagotomy plus antrectomy plus gastroduodenostomy. The studies in question were made 20 days-4 yr. after surgery, and some of the patients in each group were studied in similar fashion prior to surgery. In all 5 groups, gallbladder tonus was sharply reduced after surgery, with the most marked reduction occurring in patients undergoing vagotomy. THe degree of opacification of the gallbladder which could be obtained postoperatively was reduced appreciably, and equally, in all groups. The gallbladder's ability to contract remained essentially unimpaired in all groups, although the absolute values for initial and terminal vol. were considerably increased, indicating an inability to empty completely. This, in turn, was believed to be due to some unidentified, secondary pathology.

7642 CHOLANGIOGRAPHY WITH MECHANICAL BLOCKAGE OF THE AMPULLA OF VATER. (Fr.) Treheux, A. (Cent. Serv. Radiol., Nancy, France), J. Fays and M. Crestin. Ann. Med. Nancy 5(Nov.): 873-882, 1966.

A technic of cholangiography which involves the mechanical blockage of the ampulla of Vater by a balloon placed in the duodenum is described in detail. When this technic was applied to 31 subjects who had presented negative results when submitted to the usual i.v. cholangiographs, only 3 cases failed to give positive results. Two of these presented jaundice and the third, portal hypertension. In 3 other cases the opacification of the biliary ducts were only of medium quality, but in the remaining 25 cases the opacification was excellent. Probably the most useful application of this technic is with patients who have undergone sphincterotomies, of whom 3 cases in this report had presented strictly negative results after the usual cholangiograph, but in whom the bile ducts presented satisfactory images with this balloon technic. With this technic intrahepatic biliary ducts were also completely visible. A catheter 1.3 meters in length whose end is expandable is inserted in the duodenum so that the end of the balloon is about 1 cm from the curve of the superior genu. With the catheter in place 2 ampules of Antrenyl oxyphenonium are inj. i.v. to create a hypotonic duodenum. Afterwards the contrasting medium is inj. by a direct i.v. route (usually 20 ml). Ten min. after the inj. of the opaque soln. the balloon is expanded with 70 ml of water. The first film is taken 30 min. after this inj. and then 30, 45 and 90 min. later. The patients are made to fast for the 12 preceding hr. No complications were encountered and the intubation was well tolerated in all cases where fasting was observed.

7643 LOBECTOMY (IV) FOR THE SURGICAL EXPOSURE OF INTRAHEPATIC BILIARY DUCTS. (Fr.)

Champeau, M. Mem. Acad. Chir. (Paris) 93(4-5): 164-174, 1967.

A surgical technic for subtotal lobectomy of segment IV of the liver is described which allows clear visibility of the hepatic hilus as well as the principal pedicles, 4-5 cm of the left biliary canal and 7-8 cm of the right biliary canal, as well as more minor intrahepatic ducts. This technic includes the following stepwise procedures which allow minmum or max. displacement of segment IV: detachment of the hilus plaque just to the superior border of the bifurcation of the pedicles, freeing of the round ligament with an incision of the inferior parenchymal bridge, opening of the large hepatic fissure at the left of the origin of the middle subhepatic vein just to the level of the detached hilus sheet, then, with a transverse and perpendicular cut (digital) of the dorsal capsule, the lobe can be removed. This operation is neither traumatic nor bloody, as main vessels are not involved. In 2 cases, repair of gross liver damage was made possible by this technic; the one involving the ablation of a vesicular cancerous tumor invading the hilus area as well (papillary epithelioma) and the other allowed repair of intrahepatic biliary ducts as well as an anastomosis between the liver and intestine which again permitted good bile flow and hepatic function.

7644 CHOLANGIOCHOLECYSTOGRAPHY BY INTRAMUSCULAR INJECTION, USING SH-847. (It

Palmieri, G. C. (U. Ferrara, Italy), C. Cheli, A. Biolcati-Rinaldi and G. Voltolini. Radiol. Med. (Torino) 52(10):993-1001, 1966.

A modified form of "Bilivistan" (SH-847), with pH increased from 6.4 to 7.2-7.4 by the addition of sodium citrate, was inj. i.m. into 132 subjec of both sexes (10 ml plus 250 U.S.P. U hyaluroni into each buttock). Tolerance is reported as excellent, with minimal local or systemic allerg reactions and with good visualization of the biliary tract within 60 min. and optimal visuali tion within 2 hr. Included were patients with cholecystitis, cholelithiasis, calculi in the biliary ducts and related disorders.

7645 ANGIOGRAPHIC DEMONSTRATION OF THE ARTERIES OF THE GALLBLADDER. (Ger.)

Wenz, W. (U. Heidelberg, Germany). Fortschr. Roentgenstr. 106(3):387-392, 1967.

Among more than 70 selective angiographs of the celiac or hepatic arteries, 8 showed clearly th vascular branches of the circulatory bed of the cystic artery; improved visualization facilitat the desired differentiation of the hepatic arte proper, a condition not always technically poss A clear delineation of the wall of the gallblad is sometimes seen in the capillary phase of ser arteriography yielding information about the condition of the bladder; angiographs of a norm and an obstructed gallbladder are presented as well as the selective arteriography of a gallbladder showing tumors of the bladder and bile ducts. No comparable differentiation of change caused by stones or inflammation is possible. The topography of the cystic arteries in 3 case is described, the first a case of arteriovenous fistula, the second a case of cystadenoma, and the third, a case of cystic carcinoma. The pattern of the vascular bed showed considerable differences among these 3 cases. With differen diagnosis of late abscess following cholecystec or tumor remnants in the gallbladder celicograp should be performed; 25 ml of 76% diatrizoic ac inj. proximal and close to the point where the left gastric artery branches. The selective angiography of the celiac is superior to that of the hepatic artery.

7646 SURGICAL TECHNIC FOR BILIARY DUCT REVISION IN CHOLELITHIASIS BASED UPON 1180 CHOLEDOCHOTOMIES. (Ger.)

Kourias, B. (Greek Red Cross Hosp., Athens). Chirurg 38(5) 214-220, 1967.

The surgical technics involved in revision of the bile ducts in 1180 cases are described in detail under the headings: 1) Simple and somew difficult cases including choledochoduodenostom 2) Uncommon or complicated cases: A) coexisten of anomalies and variations of the extrahepatic bile ducts; B) spontaneous fistulas between the

llbladder and bile ducts in the liver; C)
thiasis of the intrahepatic bile ducts; D)
ronic pancreatitis; E) coexistence of liver
hinococcus with and without rupture; 3) second
multiple operations. Cholangiographies,
ken pre- and postoperatively in 80-90% of the
ses, were extremely useful. The cholangioscope,
ployed in 260 cases, was an excellent aid. No
liance was placed upon manometry because false
sults, sometimes obtained under the circum-
ances, can lead to serious mistakes. The
ical surgical methods in the removal of stones
ch as dilatation of the papillary passage,
ecific drainage, primary suturing and choledocho-
odenostomy were not adequate in many instances.
e special operative procedures, often necessary
insure good initial and lasting results, are
cribed in accounts of specific cases. Of the
0 patients 93% had operable defects and 7%
e negative. The operated cases included 146
es (12.3%) with anomalies and variations of
extrahepatic ducts; 126 cases (10.6%) having
ernal spontaneous fistulas; 96 cases (8.1%)
intrahepatic lithiasis; 98 cases (8.2%) of
onic pancreatitis; 126 cases (10.6%) of
nosing papillitis; 35 cases (2.9%) of liver
inococcus; 137 cases (11.6%) with 2 or more
rations. A number of other pathologies,
urring with less frequency, made up the total
1180; some of these were cirrhosis, cardio-
cular disorders and diabetes. The high
centage of positive findings (93%) was due to
frequency of severe and neglected cases. The
tality rate for intrahepatic lithiasis was
h (14.5%) and for reoperations, 9.49%. The
rall mortality rate for 1180 patients was
%; the lowest rate was for uncomplicated
lecystectomy, 0.43%. The early operation is
refore favorable.

7 BILIODIGESTIVE ANASTOMOSES IN THE
LIVER HILUS FOR STRICTURES OF THE
LBLADDER. SURGICAL TECHNICS AND RESULTS IN
CASES. (Ger.) Baumann, J. (City Hosp.,
sel, Germany). Chirurg. 38(5):202-209, 1967.

a total of 7500 biliary operations, 54 bilio-
estive anastomoses, performed from 2-9 yr.
, have proved to be good to very good in 83.3%
cases. In biliodigestive anastomoses involving
rahepatic bile ducts, the prospect of healing
been less the closer to the hilus the
stomosis was constructed. The favorable results
attributable to the great width of the
stomosis and the small tendency to shrinkage.
lux of food material is not harmful in view
ts rapid return into the duodenum through
wide anastomosis, regularly observed by X-
Very severe cholangitis, seen in 10 cases
mo. duration, and in 15 cases of over 26 mo.
ding, were healed; simultaneously the active
r cirrhosis arising from cholangitis and
estasis was arrested or, as in most cases in
series, healed. The basic surgical technic:
omentum, the transverse colon, the duodenum and
gastric antrum up to the free portion of the
forward wall of the stomach were freed from the inferior side of the liver so that the underside of the liver presented a wide, clear field. The duodenum was freed from the omentum and transverse colon. The transsection of the ligaments teres and falciforme followed; then the forward wall of the liver was separated from the ribs and the diaphragm, mobilizing the liver. The particular surgical procedure, from this point, varies considerably depending upon the specific case.

7648 RAPID DIAZO METHOD FOR THE DETERMINATION OF TOTAL BILIRUBIN WITH A COMBINATION OF REAGENTS. (Ger.) Hillmann, G. (City Hosp., Nuremberg, Germany) and G. Beyer. Z. Klin. Chem. 5(2):92-93, 1967.

The method of Malloy-Evelyn, modified by Rand and Di Pasqua (substitution of sulfanilic acid with 2 and 4 dichloranaline) is further modified by the substitution of ethylene glycol for methyl alcohol; ethylene glycol has the advantage of not causing precipitation of protein while having the same accelerating effect upon the formation of azobilirubin. The spectrum of the azobilirubin compound in ethylene glycol lies between 545 and 550 mμ instead of the 540-544 mμ in methyl alcohol. In the Rand and Di Pasqua method the color reaction is stable for 30-40 min.; with the use of ethylene glycol the color is stable for more than 5 hr.; measurement at 550 mμ is made after at least 2 min. to allow for the development of color. Extinction of the azobilirubin compound is proportional to the bilirubin content. For the routine microtest 0.2 ml hemolysis-free serum or plasma is used; with strongly jaundiced sera 0.1 ml is employed. Reagents: 0.01 M 2,4-dichloranaline in 0.25 N HCl; 0.1 M $NaNO_2$ in H_2O; ethyleneglycol. Diazo reagent A: 50 ml of dichloranaline soln., mixed with 1 ml nitrite soln. is placed in the refrigerator for 15 min. at 6° C after which 250 ml of ethylene glycol is added to the mixture. Reagent A keeps for 12 hr. at room temperature and for 48 hr. at 6° C. Reagent A (3 ml) is mixed with 0.2 ml of serum to be tested. Where necessary blanks and standards can be used. This test has a 98% correlation coefficient with the Jendrassik/Grof test; its sensitivity is 0.4 mg% and its precision is ± 0.2 mg% at a mean conc. of 5.7 mg%.

7649 CYTOLOGICAL STUDIES AND FUNCTIONAL DIAGNOSIS OF PANCREATIC AND BILIARY DISORDERS. (Dut.) Orsini, G. C. (Gen. Hosp., Potterdam, Netherlands), D. I. Blonk and G. J. H. Den Ottolander. Nederl. T. Geneesk. 110(48):2115-2119, 1966.

A cytologic diagnostic test of the functions of the pancreas and the biliary system was evaluated in 34 patients. Fluid was collected from the duodenum without dilution by gastric juice. The duodenal fluid was collected for a 20-min. control period, then 1 U secretin/kg body wt. was inj. i.v., and 10-min. portions of fluid were collected.

After secretion vol. had returned to normal, cholecystokinin, 1 U/kg body wt., was inj. and again duodenal fractions were collected. These portions of fluid were analyzed for pH, bicarbonate conc., bilirubin, amylase content; vol. of fractions were obtained. The combined fractions for each inj. were then centrifuged (8000 rpm) and the sediment streaked on microscope slides, air-dried and stained and carried up into mounting medium and covered. Examination of these slides yielded definite diagnoses in only 6 cases; 4 Fout-negative and 2 class III, Papanicolaou. In 4 cases where malignant changes of the pancreas and the biliary ducts were found at operation or later at autopsy, the cytologic test proved negative. Through the usual diagnostic means including the tests on the duodenal fluid, the group of 34 patients had 8 with cholelithiasis, 3 with sclerotic pancreas, 2 each with pancreatic carcinoma, splenomegaly, pancreatitis, gallbladder carcinoma, and wt. loss and 1 each with unrelated tumors, liver carcinoma, abdominal pain, pneumonia, obstructive jaundice, metastasized carcinoma, steatorrhea and hepatomegaly, and carbon monoxide intoxication.

  ascites: 7504*,7608*,7620*,7621*
  associated diseases: 7163*,7422,7613*,7624
  biliary: 7359*,7378*,7612*,7613*
  blood coagulation: 7622*
  children: 7630
  circulation: 7382*,7610*,7620*,7621*
  diagnosis: 7371*,7373*,7387*,7394*,7447, 7572*,7618*,7621*,7622*
    biochemical procedures: 7619*
  epidemiology: 7633
  etiology: 7633
  experimental studies: 7609*
  immunology: 7617*,7618*
  metabolic changes: 7395*,7397*,7607*,7615*, 7616*
  microorganisms: 7377*
  pathology: 7371*,7528*,7609*,7611*,7619*, 7622*,7632
  treatment: 6848*,7497,7608*,7612*,7614*, 7617*,7628,7629,7634
  water and electrolyte metabolism: 7614*, 7626,7627
COLITIS (see also Enteritis; Enterocolitis; Gastroenteritis): 7278,7281,7291*
COLITIS, GRANULOMATOUS (see Enteritis, Regional)
COLITIS, ULCERATIVE (see Ulcerative Colitis)
COLON (see Intestine, Large)
CONSTIPATION: 7165*
CORTICOSTEROIDS: 6666*,6680*,6706*,6802,6805, 6911*,7122*,7162*,7170*,7206*,7348,7393*, 7557*,7558*,7560*,7561*,7570*,7582*,7613*, 7614*,7690
CROHN'S DISEASE (see Enteritis, Regional)
CYSTIC FIBROSIS (see Mucoviscidosis)

DEFECATION: 7165*
DIAGNOSTIC PROCEDURES (see under Gastrointestina Tract, diagnosis; specific organs and diseases)
DIAPHRAGM (see also Hernia, diaphragmatic)
DIARRHEA: 6854,6884,6889,6910*,6911*,6917, 6948,6949,6952,7124*,7156,7165*
DIETOTHERAPY (see under Nutrition)
DIGESTION (see also Bile; Intestine, Small; Pancreas): 6888
  carbohydrate: 6676*,6677*,6705*
  lipid: 6641,6738*,6741,7312*,7313*
  protein: 6705*,6727,6735*,6736*
DIVERTICULA (see under specific organs)
DIVERTICULITIS (see under specific organs; Malabsorption)
DUMPING SYNDROME (see Gastrectomy, complication dumping syndrome)
DUODENUM (see also Intestine, Small): 6638, 6643*,6645*,6756,6852,6864,6912*,6992,7083, 7117*,7127,7148,7203,7335*,7670
  diseases (see also under Ulcer)
DYSENTERY (see also Amebiasis; Shigellosis; Typhoid Fever): 6946,6950
  diagnosis
    biochemical procedures: 6951
  treatment: 6877,6886,6892

RYOLOGY (see development under specific organ
and Gastrointestinal Tract)
SIS (see Vomiting)
OSCOPY (see diagnosis under specific organ)
ERITIS (see also Colitis; Enterocolitis;
Gastroenteritis): 6878,6890,7206*
ERITIS, REGIONAL
Crohn's Disease of colon (granulomatous
  colitis): 6846*,7199*,7200*,7201,7202,
  7203,7289*,7290*,7295
EROCOLITIS (see also Colitis; Gastroenteritis):
7237*
Escherichia coli: 6838*,6890,6947,6950,6958
treatment: 6890
YMES, MISCELLANEOUS (see also Amylase; Liver,
enzymes, parenchymal; Pancreas, secretion;
Phosphatase; Stomach, secretion, pepsin):
6739,6935,6950,7059,7137,7222,7536
PHAGITIS: 6849*,6977,6993*,7026
PHAGUS (see also under Achalasia; Hernia)
anomalies: 7003,7004,7005,7010
associated diseases: 7050*
children: 6646*,7008,7014
circulation: 6646*,6998*
diagnosis
  biochemical procedures: 6999*
diseases: 6849*,7050*
fistula: 7005,7009,7010

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

NUMBER AND SEPARATION OF ENZYMES IN THE
MUCOSA OF THE GASTROINTESTINAL TRACT OF
I!. . HISTOCHEMICAL AND SUPPLEMENTARY
ES ON ISOENZYMES. (Ger.) Klein, U. E. (U.
Kiel, Germany), H. C. Drube and H. T.
en. Klin. Wschr. 45(2):95-101, 1967.

sal tissue was taken at operation from the
ach, the duodenal bulb and the first loop of
jejunum; tissue was also obtained by biopsy
the duodenum, jejunum and rectum. Patients
ileostomies furnished samples from the ileum.
tissues were used freshly frozen or kept
en at -20°C for periods up to 2 wk. Frozen
ions were mounted on coverslips and histo-
ical tests were made for the various enzymes.
isoenzymes of alkaline phosphatase were
ated by extraction of homogenates, electro-
esis, and staining, before and after fat
ing; alkaline phosphatase was also determined
he chyle of the thoracic duct of 1 patient.
ll mucosal samples unspecified esterases,
phosphatase, thiamine pyrophosphatase,
inic dehydrogenase and LDH were demonstrable.
in the small intestine did sucrase, lactase,
line phosphatase, leucine aminopeptidase, and
osine triphosphatase (ATPase) appear and
ease in conc. (not equally). The parietal
s of the gastric mucosa showed more intense
tions for the enzymes present than did the
f cells. The 2 different sites of enzyme
lization in the small intestinal epithelium
the crypts of Lieberkühn and the villi; the
i and especially the apical epithelium showed
conc. of leucine aminopeptidase, alkaline
phatase ATPase, and were the only cells hav-
disaccharidases. All the enzymes found in
stomach were present in the rectum. In the
enum, alkaline phosphatase, leucine amino-
idase, ATPase and disaccharidases were
eased in cells with brush borders, although
capillary and vascular endothelium in these
ons had unchanged intensive color reactions
alkaline phosphatase, and ATPase. The
line phosphatase of the small intestine was
rated into 3 fractions which were inhibited
-phenylalanine, distinguishing the intestinal
line phosphatase from those of other tissues
ot so inhibited. The chyle from the thoracic
possessed 2 fractions of alkaline phosphatase
ating toward the anode of the electrophoretic
d, the slower migrating at the same rate as
middle fraction of the small intestinal
line phosphatase; and like this intestinal
tion, inhibited by L-phenylalanine; the
er fraction had the characteristics of serum
line phosphatase. Oral fat-loading intensi-
the 3 intestinal fractions of alkaline phos-
ase, especially the middle one, but had no
ct upon serum alkaline phosphatase. The
acellular localization of the enzymes is
ribed in detail.

EFFECTS OF RESERPINE ON THE DIGESTIVE TRACT OF ANIMALS. (Rus.) Smejkal, V. (Res. Inst. Pharm. Biochem., Prague). Biull. Eksp. Biol. Med. 63(2):64-67, 1967.

Reserpine (0.25 mg/kg) was admin. i.p. to male Wistar rats (150-200 g) on the first, third and fifth days of the experiment; methoxyphenoserpine (in a dose, unspecified, producing catharsis) was given on the sixth day. The relationship of blood pressure to gastric motility was studied in Chinchilla rabbits (both sexes; 2-3 kg wt.); neostigmine (12.5 µg/kg) was admin. i.v. to control and experimental animals 30 min. before the admin. of reserpine (1 mg/kg). The first 2 doses of reserpine induced catharsis in 9 of 10 rats, but the third dose produced this effect in only 1 rat. Similar results were obtained with methoxyphenoserpine (10 mg/kg, admin. i.p.). Catharsis disappeared after admin. of reserpine on the sixth day. There was no correlation between changes in blood pressure and gastric motor activity. Similar results were obtained with methoxyphenoserpine. The lack of correlation between changes in blood pressure and changes in gastric motor activity in rabbits after admin. of reserpine indicates that this drug acts differently on the cardiovascular system and the gastrointestinal tract.

7706 ANAPHYLACTOID REACTION AND THE INTESTINAL MUCOSA. (Hun.) Ihász, M. (University of Budapest, School of Med.), J. Füsy, G. Karika and I. Kiss. Kiserl. Orvostud. 18(6): 608-611, 1966.

One-ml amounts of various dilutions of 3.5% polyvinylpyrrolidine in Ringer's soln. were inj. into the mesenteric artery of fasting dogs (15-20 kg) under narcosis. The intestinal mucosa was observed in situ. Approx. 1 min. after admin. of the polyvinylpyrrolidone the movement of the villi stopped for 2-3 min. During this time the villi contracted and the secretion of the mucosa increased. However, the arterial blood pressure did not change. The normal movement of the villi returned after another min. Similar, but less pronounced, effects were observed with higher dilutions of the drug. When large amounts of drug were inj. into the femoral vein, a general anaphylactoid reaction was induced, e.g., 3 min. after admin. of 1 ml/kg of the soln., the arterial pressure as well as the movement of villi began to decrease in parallel. The former reached a minimum 5-6 min. later. At that time the villi contracted and their movement stopped. The intestinal mucosa became slightly anemic and its secretion increased. Thereafter the blood pressure increased gradually and the movement of the villi was restored. However, some of the animals who received high doses of the drug died. Control experiments revealed that local application of polyvinylpyrrolidone did not affect the function of the intestinal mucosa.

GENERAL

7707 CHLORTETRACYCLINE AND MOUSE INTESTINAL WALL. (E.) Rosen, H. (Walter Reed Army Med. Ctr., Washington, D. C.), A. Einheber, N. D. Brown and R. E. Wren. Nature (London) 214(5089):671-674, 1967.

Each mouse received either 100 mg/kg freshly prepared chlortetracycline or an equivalent wt. of sterile 0.9% saline i.p. for 6 consecutive days. Germ-free mice (Group 1) were compared with "conventionalized" mice (Group 2). Tissues were assayed for histamine and serotonin. Body wt. were essentially the same for both groups of the same sex, but the cecum and the small and large intestines were heavier (on a body wt. basis) in Group 1 of either sex, the difference being more marked in females. Females in Group 2 showed the greatest gains in wt. of both the small and large intestine. The serotonin conc. of intestinal tissue increased only in Group 2 females, and decreased in all other groups. The histamine conc. in all the intestinal segments decreased in all groups, the decrease being greatest in females. The unique reaction of Group 2 to the drug was also shown by their severe body wt. losses (13%), large loss of spleen mass (38%), and by the fact that 2 died. The males in Groups 1 and 2 and females in Group 1 lost only 5%, 5%, and 3% of their control body wt., resp., and 8%, 8% and 5% of their control spleen wt.; there were no deaths among them. It appears that a mechanism is operative in females which renders them more liable to chlortetracycline-induced intestinal changes irrespective of their microbial status, and that the absence of a microbial flora modifies and/or attenuates these changes. Chlortetracycline-induced changes in intestinal serotonin and histamine did not correlate with concomitant changes in intestinal mass. In reference to use of this drug in humans, it is suggested that the reported gastrointestinal upsets may be caused not by alterations of the intestinal flora alone, but also by alteration of the serotonin and histamine levels in the intestinal tract tissue.

7708 INHIBITION OF PROTEIN SYNTHESIS IN RAT INTESTINAL SLICES BY TETRACYCLINE. (E.) Greenberger, N. J. (Ohio State Univ. Coll. Med., Columbus). Nature (London) 214(5089):702-703, 1967.

Female rats, fasted for 16 hr., were given either saline (controls, 12) or tetracycline (400 mg/kg, i.p., 10). Protein synthesis was measured by the incorporation of ^{14}C-leucine in jejunal slices. There was a statistically significant decrease in incorporation of the label into protein by jejunal slices obtained from experimentals (109.5 X 12^{-12} M/0.5 g jejunal slice) as compared with controls (155.2). Results indicate that tetracycline treatment may result in inhibition of protein synthesis in intestinal mucosa. It is suggested that this tetracycline effect might be due to inhibition of amino acyl-sRNA binding to ribosomes.

7709 SOME OBSERVATIONS ON 'AUTOREGULATORY ESCAPE' IN CAT INTESTINE. (E.) Bake R. (King's Coll., London) and D. Mendel. J. Physiol. (London) 190(1):229-240, 1967.

Studies were carried out on anesthetized cats determine the mechanism of autoregulator escap and its relation to the opening of the shunts, whether the escape is associated with sympathe nerve stimulation or whether it also occurs wh intestinal blood is reduced by other means, whether intestinal movement is involved, or whether an alteration in local pH causes any of sensitivity to sympathetic amines. The sympathetic nerves in the sheath around the superior mesenteric artery were prepared for stimulation. The main mesenteric artery (divi into 3 branches for the experiment), the splen vein, femoral artery and vein (and superior mesenteric vein when necessary) were prepared for cannulation. The animals were heparinized Blood flow to the intestine was measured with the density flowmeter method, with a modified circuit (2 double triode valves controlling 2 multicontact relays); accuracy was within ± 3% over the range 1-40 ml/min., with a pressure drop of 1 mm Hg at the highest rates of flow. Resting flow through the intestines ranged fro 6-32 ml/min. at an av. pressure of 90 mm Hg. The av. initial O_2 consumption was 0.91 ml/min 100 g. "Escape" was found to be peculiar to norepinephrine infusion and splanchnic nerve stimulation, and was not observed during hemorrhage or obstruction of the arterial infl with a screw clip. Flow recovery during norep phrine infusion was not explained by intestina motility changes or long norepinenephrine effe (caused by changes in portal venous pH). An initial reduction in O_2 consumption and a fall blood pressure during norepinephrine infusion, was followed by increased O_2 consumption durin the period of "autoregulatory escape." Portal venous pH and O_2 content were also measured. A clear explanation of the escape mechanism wa not found, but it was suggested that a number possibilities were eliminated.

7710 CHANGES IN THE EXCITABILITY OF THE INTEROCEPTORS OF THE SMALL INTESTINE ANAPHYLAXIS (AN ELECTROPHYSIOLOGICAL STUDY). (Rus.) Lebedeva, V. A. (Pavlov Inst. Physiol. Acad. Sci., Leningrad, USSR), B. I. Padegimas and I. L. Pines. Biull. Eksp. Biol. Med. 63(3) 44-48, 1967.

This study was performed on 22 cats under urethane narcosis (1.0-1.5 g/kg). In control cats (10), spontaneous afferent impulses were usually absent or slight in nerves of the small intestine. In sensitized animals (1.5 ml of horse serum given s.c. 4 times with a 1-2 day interval between each admin.) a pronounced spontaneous activity was noted in the form of slow fluctuations (with an amplitude up to 20 µVolts) and rapid oscillations of 1-2 msec. duration (an amplitude of 30-40 µ Volts).

nsitized animals were intestinally perfused
Ringer-Locke soln. and the av. threshold
of acetylcholine which increased afferent
ity were 10 μg; addition of horse serum (5
o the perfusion fluid did not alter activity
ensitivity of receptors to acetylcholine re-
d unchanged; impulses were stimulated only
the admin. of 100 μg or more of acetylcholine
e systemic circulation. Reaction of recep-
was absent upon i.v. admin. of horse serum,
heir sensitivity to the subsequent admin.
etylcholine remained unchanged. In the
tized cats the threshold doses of acetyl-
ne which stimulated receptors during admin.
the perfused intestine decreased to 0.1
The admin. of horse serum with the perfusion
stimulated activity. Horse serum decreased
itivity of the intestinal receptors to acetyl-
ine more than 100-fold, and the av. threshold
s of acetylcholine admin. into the systemic
ulations were 100 μg. Horse serum admin.
stimulated afferent activity after excit-
ity of the intestinal receptors decreased
tylcholine threshold doses increased to
1000 μg). Electrophysiological study of the
tional status of the small intestinal recep-
showed that, in animals sensitized by
ated admin. of heterogenic horse serum pro-
, the receptor excitability was markedly
er than in controls. These data suggest a
ible participation of interoceptors of the
l intestine in the sensitization of the
nism and in the mechanism of anaphylactic
k.

CHANGES IN GLUCOSE METABOLISM IN THE RAT
INTESTINE THROUGH ADAPTATION TO A PRO-
-RICH DIET. (Ger.) Scharrer, E. (Harvard
Boston, Mass.), K. Müller and H. Zucker.
e Seyler. Z. Physiol. Chem. 348(6):720-722, 1967.

ose metabolism was monitored in rats which
been adapted to a high-protein (74%) diet,
in rats adapted to a low-protein (11%) diet;
protein in these diets was methionine-enriched
ein; oil, minerals, and vitamins as well as
ohydrate were in the diet. The animals were
the 2 different diets for an adaptation period
3 wk. After a 24-hr. fast the animals each
eived 3 g of high-protein diet. The blood
ar levels were measured every 1 or 2 hr. for
hr. in the blood from the abdominal aorta,
portal vein, and the inferior vena cava. The
y significant difference occurred between the
cose levels in the aorta and portal vein of
group adapted to a high-protein diet compared
the difference of the group adapted to a low-
tein diet. The blood sugar level in the portal
n of the protein-adapted animals was high,
icating reduced glucose utilization by
estinal tissue following protein adaptation.
dy of isolated small intestine confirms this.

2 TISSUE ANTIGENS OF THE DIGESTIVE TRACT
IN MAN AND ANIMALS. I. ANTIGENS
ATED TO THE AGGLUTINOGENS OF A BLOOD GROUP.
.) Zweibaum, A. (Broussais Hosp., Paris), B.
pern, C. Veyre and R. Oriol-Palou. Path. Biol.
ris) 15(7-8):349-358, 1967.

Tissues were obtained from the various regions of the digestive tracts of rats, normal and germ-free, from fetal animals by cesarian section between 18-21 days of gestation, as well as from dogs, rabbits, monkeys, guinea pigs, pigs; horses, cattle, sheep and cats. Specimens of human mucosa were obtained at operation and at autopsy. All tissues were immediately frozen in liquid nitrogen. Human sera of 400 subjects representing the 4 international blood groups were provided from normal donor blood. Immune sera were developed in rabbits. Controls and proofs of absorption were used throughout these studies. Fluorescent immune sera for the indirect technic of Coons were developed using rabbit immune sera with a modification of technic giving constant results of complete specificity. Colonic mucosa (obtained from an animal with the demonstrable antigen) was inj. into rabbits or rats; the immune sera, with a very high titer of specific agglutinins against human group A agglutinogen, were developed and used with the Coons' method and Goldstein's technic. The mucous glands of the colon of some species of animals (all except the guinea pig and the horse) had an antigen immunologically related to, or identical with, the human A agglutinogen of RBC. The agglutinogen is not of bacterial origin as was proved in germ-free animals and by fetuses. It is different from the Forssman heterophil antigen. It was found in the gland cells of the digestive tract but not in the RBC. Immune sera against the colonic mucosa from an animal with the antigen had high specific titers of specific agglutinins against human group A RBC, confirming the close immunologic relationship between the antigens of the mucous glands and the Group A human RBC. In the rat, dog, cat rabbit, monkey and sheep the A-agglutinogen was mainly confined to the glands of the colon, but was occasionally demonstrated in the small intestinal glands. It was never found in the prepyloric region of the tract in these animals. However, in the ox, horse, swine and man (Group A) the agglutinogen was constantly present in the prepyloric part of the digestive tract and more rarely, except in the pig, in the ileum and colon. With respect to the A agglutinogen these mammals can be divided into gastric and colonic secretors.

7713 TISSUE ANTIGENS OF THE DIGESTIVE TRACT IN MAN AND ANIMALS. 2. THE ANTIGENS OF THE COLON. (Fr.) Zweibaum, A. (Broussais Hosp., Paris), B. Halpern, C. Veyre and R. Oriol-Palou. Path. Biol. (Paris) 15(7-8):359-367, 1967.

The same material and methods used in the previous paper have been used in these studies. The immuno-fluorescent method of Coons with Goldstein's technic were the main investigative technics. Direct methods were sometimes insufficiently sensitive. Specific details of the methods are given. The immunological nature of the antigens present in the mammalian colon was studied by immunizing animals with homologous and heterologous colonic mucosa and by investigating the nature and specificity of the antibodies thus obtained. Qualitative and quantitative studies of immune sera obtained by the use of colonic mucosa of 10 species of animals, including man, demonstrated 3 specific kinds of colonic antigens: (1) species-specific anticolonic antibodies; (2) organ-specific antibodies common for all mammals; (3) antibodies specific for an antigen related to human blood group A agglutinogen, present in the colon of certain species of animals only (previous paper). Immunization with homologous colonic mucosa never caused formation of anticolonic antibodies. Immunization with heterologous colonic mucosa produced antibodies which were fixed not only by heterologous colons but also by the immunized animal's own colon. A hypothesis is advanced that the interspecific cross reactions are probably caused by antigens of mucopolysaccharide type which exhibit very similar immunologic relationships.

7714 VITAMIN D STIMULATION OF [^{3}H]-OROTIC ACID INCORPORATION INTO RIBONUCLEIC ACID OF RAT INTESTINAL MUCOSA. (E.) Stohs, S. J. (U. Wisconsin, Madison), J. E. Zull and H. F. DeLuca. Biochemistry (Wash.) 6(5):1304-1310, 1967.

Male weanling rats were fed a diet adequate in Ca (0.47%) and P (0.3%), and given fat-soluble vitamins p.o. thrice weekly; the rats were vitamin D-deficient after 3-4 wk., as shown by reduced growth and lowered serum Ca levels. In experiments in which rachitic rats were used, male weanlings were maintained for at least 3 wk. on a high Ca:P ratio diet. Two vitamin D-deficient rats, fasted 12-14 hr., were given either 2,000 International U of vitamin D$_3$ i.p. in 0.5 ml of aqueous soln. containing 0.9% NaCl and 0.1% Tween 40 or 10 International U intrajugularly in 0.04 ml of 95% ethanol. Two deficient animals were used as controls and were given the appropriate soln. without the vitamin. All rats were given 50 μC of [^{3}H]-orotic acid 1 hr. before sacrifice. Several animals were admin. 100 μg of actinomycin D (i.p., in 0.5 ml of freshly prepared H_2O-ethanol (9:1) soln.) 2 hr. before admin. of vitamin D$_3$ or control soln. and were sacrificed 5 hr. later. There was a 2-3-fold stimulation of [^{3}H]-orotic acid incorporation into the RNA of intestinal mucosa within 3 hr. after admin. of vitamin D$_3$; max. response occurred at 3-5 hr. By 8 hr. after vitamin D$_3$ admin., no effect of the vitamin on RNA synthesis was observed. A stimulation of [^{3}H]-orotic acid incorporation into RNA occurred also after a 10-U intrajugular inj. of vitamin D$_3$, but a much longer lag-period was noted. One hr. after a dose of [^{3}H]-orotic acid and 3 hr. after 2,000 U of vitamin D$_3$, an increase in RNA labeling of microsomes and cytoplasm, but not mitochondria, occurred. [^{3}H]-Orotic acid was incorporated into the pyrimidine moieties of RNA. Vitamin D$_3$ stimulation of RNA synthesis was also observed in rats fed a high Ca rachitogenic diet. Actinomycin D completely blocked vitamin D$_3$ stimulation of RNA synthesis. RNA labeling was also stimulate by vitamin D in liver and kidneys, but to a muc smaller degree. It is concluded that the physi gic expression of vitamin D action involves tra lation of genetic information through RNA to functional components.

7715 PHYSIOLOGY OF THE SMALL INTESTINE. (E.)(Rev.) Jordan, P. H., Jr. (Baylo Univ. Coll. Med., Houston, Tex.). Surg. Gynec. Obstet. 124(6):1331-1338, 1967.

7722 DEMONSTRATION OF HUMAN REAGIN IN MONKE TISSUES. III. IN VITRO PASSIVE SENSITIZATION OF MONKEY ILEUM WITH SERA OF ATOPI PATIENTS. PHYSIOLOGIC AND ENHANCING EXPERIMENTS (E.) Kobayashi, S. (State U. New York, Buffalo) J. P. Girard and C. E. Arbesman. J. Allerg. 40(1):26-45, 1967.

LOCALIZATION OF LYSOZYME ACTIVITY IN A PANETH CELL GRANULE FRACTION. (E.)

, R. J. (Univ. Hosp. St. Rafael, Louvain,
um), G. R. Vantrappen and M. M. Parein.
im. Biophys. Acta 139(1):204-207, 1967.

id increase in lysozyme was observed in small
tinal fluid of mice and cats after admin. of
arpine. Because of the analogy of histo-
cally determined characteristics of the
h cell granule content and lysozyme, it was
ed that the Paneth cell granule contains the
e. Homogenates of mouse and cat small
tine mucosa were fractionated by differential
ifugation. A Paneth cell granule rich frac-
containing a max. of lysozyme activity was
ted from mice, but not cats. Paneth cells
resent in mice, not in cats. Mucosa-free
intestine segments from mice and cats were
enated in sucrose and centrifuged for 450
tion 1), 12,000 (2), 47,200 (3), 180,000
4.5 x 10^6(g x min) (5) and the supernatant
Half of Fraction 2 was purified on an ion-
nge resin and the eluate centrifuged for
0 g (purified Fraction 2). Histological
ons and sedimented subcellular fractions were
ed with hematoxylin-eosin and Gram stains for
scopic examination. Granules with morpho-
al and stain characteristics of Paneth cell
les were mainly in Fraction 2, somewhat in
the mouse. Analysis of DNA, RNA, protein,
yme, monoamine oxidase, β-glucuronidase, acid
hatase and alkaline phosphatase showed Paneth
granules only in 2. A peak of lysozyme
ity was found in 2, and to a lesser extent
Specific activity of lysozyme in purified
ion 2 was 3 times that in unpurified Fraction
raction 5 did not show this change on treat-
Osmotic shock showed that, in a hypotonic
m, lysozyme was released from 2 but not 5.
ts suggest that lysozyme is specific to
ion 2 and is probably found in the Paneth
granules. Lysozyme in 5 may be due to
rostatic binding to microsomes. Lysozyme
ity was low or absent in cat fractions.

SULFATE-CONTAINING MUCOSUBSTANCES OF DOG GASTRIC MUCOSA. (E.)

Spicer, S. S.
, Bethesda, Md.), T. J. Leppi and J. G.
on. Lab. Invest. 16(5):795-802, 1967.

s closest to the lumen, and of neutral muco-
tance in mucous neck and parietal cells,
esponded with absence of autoradiographic
ence for isotope incorporation in these sites.
Digestion with bovine testicular hyaluronidase partially eliminated basophilia of the sulfated mucosubstance in the chief cells and cardiac glands and abolished that of the sulfomucin in the pyloric glands. Hyaluronidase did not, however, alter basophilia of the surface epithelium and had no effect on the strong periodic acid-Schiff reactivity of secretion in the pyloric glands. The basophilia of all dog gastric mucins is eliminated by a 4-hr. 60° C methylation.

7725 INFLUENCE OF IMMUNOSYMPATHECTOMY ON BOWEL ARGENTAFFIN CELLS. (E.)

Thompson, J. H. (U. California Sch. Med., Los Angeles). Arch. Path. (Chicago) 83(5):415-418, 1967.

Swiss-Webster white mice were divided into three groups. Group 1 (5 males, 3 females) was inj. s.c. on the first 6 days of life with 0.02 ml nerve growth factor antiserum/g body wt. and thereby immunosympathectomized; Group 2 (4 males, 4 females) was handled but no inj. was made; and Group 3 (9 males, 5 females) served as normal controls. After sacrifice (which was always done between 8-9 A.M. on the day of study to minimize circadian differences in intestinal serotonin levels or argentaffin cell granulation), the conc. of argentaffin cells in gastrointestinal mucosa was determined for the esophagus, gastric fundus, body and pyloric antrum, upper and lower duodenum, midjejunum, middle and terminal ileum (last half inch), appendix (cecal tip), ascending and descending colon and proximal rectum. There was no significant difference between the cell count per 100 intestinal crypts, or gastric pits in comparable tissues. It is suggested that the increased conc. of serotonin in some areas of the mouse intestine after immunosympathectomy (previously reported) may be due to an increased level of the amine per cell, rather than an increase in the population of argentaffin cells.

7726 PERFUSION AND IMMERSION FIXATION OF RAT LIVER WITH GLUTARALDEHYDE. (E.)

Fahimi, H. D. (Free U., Brussels). Lab. Invest. 16(5):736-750, 1967.

The fixation of rat (male, Sprague-Dawley) liver by immersion and perfusion with glutaraldehyde was studied. Immersion fixation in the conventional manner for 3 hr. in 2.5% glutaraldehyde in phosphate buffer fixed only a thin rim of 5-10 cell layers at the periphery of the tissue block. Direct perfusion of the same glutaraldehyde fixative through the portal vein often resulted in thrombosis of branches of the portal vein and poor perfusion fixation. There was significant improvement when brief perfusion of heparinized saline preceded perfusion of the fixative through the portal system. However, it was found that perfusion of the fixative through the portal vein followed by perfusion through the hepatic vein yielded the best results in a large percentage of animals. It is concluded that, considering that a 10- to 15-min. fixation appeared to be sufficient, the perfusion fixation of rat liver may be useful for future ultrastructural, cytochemical and biochemical studies.

7727 STRUCTURE OF THE COMMON BILE DUCT IN MAN: PRESENCE OR ABSENCE OF SMOOTH MUSCLE. (E.) Mahour, G. H. (Mayo Clin., Rochester, Minn.), K. G. Wakim, E. H. Soule and D. O. Ferris. Ann. Surg. 166(1):91-94, 1967.

A survey of the medical literature has revealed varied descriptions concerning the structure of the common bile duct in man; the presence or absence of the smooth muscle in the duct and its function with regard to the passage of bile have been debatable. Common bile ducts were removed at postmortem examination from 100 selected subjects (13-94 yr. old), each of whom had a normal hepatobiliary duct system. Histological examination revealed that 88% had no smooth muscle fibers at all in the duct wall, whereas the remaining 12% had smooth muscle clearly demonstrated in the wall of the duct. Quantity of smooth muscle fibers varied among specimens, but except for 1 specimen, such fibers were always observed in sections from both the distal and the proximal segments. One duct showed muscle fibers in the section from the distal part but no muscle fibers in the proximal portion. The muscle fibers were always sparse and interdigitated with the collagenous and elastic fibers. There was no relationship between the age of the subject and the presence or absence of smooth muscles in the structure of the ducts, nor did the distal segment exhibit more muscle than did the proximal one.

ABSORPTION OF EXOGENOUS AND ENDOGENOUS BILIARY COPPER IN THE RAT.

(E.)
r, P. (U. Sydney, Australia) and S. P.
lis. *Nature* (*London*) 213(5073):291-292, 1967.

received 0.5-1000 μg ^{64}Cu as cupric acetate
oper (II-ethylenediaminetetraacetic acid)
killed after 24 hr., the entire gastro-
tinal tract resected and the total radio-
ity remaining in the carcass, liver and
used as an index of absorption. For ab-
ion of biliary Cu, bile was first obtained
gh an external biliary fistula from rats
ously admin. 100 μg Cu i.v. Known amounts
in the biliary fractions taken at 0-4, 4-8
-24 hr. (both dialyzed and undialyzed) were
intrapylorically and absorption determined
24 hr. Absorption of 2.5 μg ceruloplasmin
rom donor rats) was also determined. About
f Cu was retained when cupric acetate was
. at 0.5-10.0 μg. Absorption decreased
increasing dose, and was 10% at 200-1000 μg.
ar results were obtained with the other Cu
und. With inj. of biliary Cu at 0.5-10.0 μg,
% was absorbed in 24 hr. At a constant dose
5 μg endogenous undialyzed biliary Cu, ab-
ion decreased progressively when the frac-
of bile taken at later times were inj.
of absorption for 0-4 hr. fraction, 9% for
hr.). After ceruloplasmin, approx. 10% of
was retained. The poor absorption of
enous Cu is contrasted with the far greater
ption of exogenous Cu. The differing degree
sorption with a constant amount of biliary
ggests a change in the Cu-protein complex
increasing time after i.v. admin. The re-
might explain the zero Cu balance in man
te a relatively high intake of dietary Cu.
sive exogenous Cu is poorly absorbed. Sub-
nt biliary excretion and poor reabsorption
, i.e. lack of significant enterohepatic
lation, may represent the chief pathway for
limination of Cu from the body.

THE ABSORPTION OF CALCIUM CARBONATE.

(E.) Ivanovich, P. (U. Washington
Med., Seattle), H. Fellows and C. Rich.
Intern. *Med*. 66(5):917-923, 1967.

ngle dose of 1-12 g of $CaCo_3$ given to normal
ing subjects caused a transient rise of blood
onc., often to low hypercalcemic values;
rise was greater and more prolonged after the
er doses. In order to evaluate directly the
rption of this salt of Ca, 2 g of $CaCO_3$
led with ^{45}Ca were admin. p.o. to fasted sub-
s; all patients had normal blood Ca values
he time this test was done. Five control
ects absorbed 9-18% of the dose, while 5
ents with acute milk-alkali syndrome absorbed
een 12-37% of the dose. A third group of
patients, found to have no free acid, absorbed little or no $^{45}CaCO_3$. One of these patients admin. 50 mg betazole s.c. 45 min. before $^{45}CaCO_3$ was given for a second measurement of absorption; as compared to the first test, gastric pH dropped from 6.5 to 1.0, acid conc. rose from 14 to 110 mEq/liter and the absorption of $^{45}CaCO_3$ rose from 2 to 10%. A control subject, similarly stimulated, showed a probably significant but less marked increase in absorption from 15 to 19% of dose. From this it was concluded that gastric acid must be present to dissolve the $CaCO_3$ before it can be absorbed. The percent absorption of 10, 200 and 500 mg Ca, given as Ca gluconate to subjects with normal Ca metabolism and gastrointestinal function, was 67.5 ± 24.3, 24.6 ± 8.7 and 21.8 ± 4.3, resp.; the 2 g dose of $^{45}CaCO_3$ contained 800 mg Ca, and its absorption was 16.6 ± 8.5%. These results show that $CaCO_3$ is as well, or almost as well, absorbed as calcium gluconate and support clinical evidence that treatment with $CaCO_3$ leads to hypercalcemia in some patients and ultimately, in a few, to irreversible renal damage and Burnett's syndrome. The only subjects who failed to absorb $CaCO_3$ were patients who were found not to secrete free acid in their gastric juices.

7743 INTESTINAL TRANSPORT OF CALCIUM AND PHOSPHATE IN EXPERIMENTAL MAGNESIUM DEFICIENCY.

(E.) Lifshitz, F. (Johns Hopkins U. Sch. Med., Baltimore, Md.), H. C. Harrison and H. E. Harrison. *Proc*. *Soc*. *Exp*. *Biol*. *Med*. 125(1):19-25, 1967.

Male weanling Sprague-Dawley rats (of dams which were deprived of vitamin D during lactation) were divided into 4 groups: a control and a Mg-deficient group from both vitamin-D-treated and vitamin D-deficient animals. All rats were fed a vitamin-D free diet that differed only in the Mg content (controls, 0.397 mg/g of diet; Mg-deficient, 0.022 mg/g of diet). In addition, the vitamin-D-treated animals received 100 or 1000 I.U. of vitamin D_2 in a single dose p.o. given weekly. The concentrative transport of Ca by everted intestinal loops *in vitro* and the permeability of the small intestinal wall to this ion were determined in intestinal preparations from these rats. Results of these experiments indicated that concentrative transport of Ca by rat small intestine *in vitro* was altered by the presence or absence of Mg in the medium, but not by Mg depletion of the animals. Permeability to Ca of the intestinal preparations was not influenced by Mg deficiency. The effects of Mg depletion of the rat and of the presence of Mg in the medium on concentrative transport of inorganic phosphate by the small intestine *in vitro* were also investigated. Concentrative transport of phosphate by intestinal loops incubated in Mg-containing buffer was less than that by those incubated in Mg-free buffer. Intestinal loop preparations from Mg-deficient rats transferred phosphate to a greater extent than those obtained from control rats; this difference was observed both in the presence and absence of Mg in the buffer soln. Mg deficiency in the rat also reduced the conc. of serum P and increased the excretion of phosphate in the urine. These results are consistent with the hypothesis that Mg influences the phosphate transport systems which control phosphate conc. in extracellular fluids.

7744 VITAMIN D-INDUCED CALCIUM BINDING FACTOR IN RAT INTESTINAL MUCOSA. (E.) Kallfelz, F. A. (New York State Vet. Coll., Ithaca), A. N. Taylor and R. H. Wasserman. Proc. Soc. Exp. Biol. Med. 125(1):54-58, 1967.

Male Sprague-Dawley rats (100 g) were fed a rachitogenic diet consisting of 50% cornstarch, 20% dextrose, 15% alcohol-extracted blood fibrin, 4% brewers yeast, 3% $CaCO_3$, 7% vitamin A palmitate in corn oil (100 I.U./ml) and 1% salt mixture; the latter contained 50% iodized NaCl, 44% KCl, 2% ferric phosphate, 1.7% manganese sulfate (dried), 2% magnesium carbonate and 0.3% cupric sulfate (anhydrous). The Ca and P conc. of the diet were 1.17% and 0.07%, resp. After 4 wk. of this diet, the rats had gross and histological evidence of rickets, and responded to vitamin D treatment with a rise in blood Ca, remission of rickets and an increase in intestinal absorption of Ca. Approx. 72 hr. before the experiment, 10 animals were given vitamin D_3 (500 I.U., p.o.) in 1 ml of a vegetable oil carrier and another 10 rats were given 500 I.U. of vitamin D_2. The p.o. admin. of vitamin D_2 or D_3 resulted in the elaboration of a Ca-binding factor which could be detected in the supernatant fraction of duodenal mucosal homogenates at 72 hr. after admin. of the vitamin. This factor was associated with the initial or protein-containing portion of the supernatants after percolation through Sephadex G-25, thereby indicating that the factor is a macromolecule, presumably a protein. Further separation of the supernatants by Sephadex G-100 gel filtration showed that the increased binding activity seen after vitamin D admin. was principally associated with only 1 of the protein peaks present in the Sephadex G-100 fractions. This particular peak was much less prominent in the fractionated supernatant of the mucosal homogenates from rachitic rats. It is concluded that the vitamin D-dependent binding activity is due to the presence of a specific Ca-binding protein in the supernatant fraction of duodenal mucosal homogenates from vitamin D-treated rachitic rats.

7745 THE ESSENTIAL ROLE OF BILE IN THE INTESTINAL ABSORPTION OF CHOLESTEROL. (E.) Buchwald, H. (U. Minnesota Med. Sch., Minneapolis) and R. L. Gebhard. Surgery 61(5): 791-794, 1967.

The absence of bile from the intact intestinal tract of the rabbit leads to essentially complete absence of cholesterol absorption. Th role of bile in the absorption of cholesterol from the intestinal tract was observed in bilia fistula rabbits, comparison being made with nor animals acting as controls. Cholesterol absorption was measured by whole-blood cholesterol radioactivity and cholesterol-specific activity subsequent to a standard intragastric dose of cholesterol-4-^{14}C. The av. 6-day whole blood values of controls were 2458 counts/min./ml.; specific activity values were 2735 counts/min./ External biliary-fistula rabbits gave values of 8.5 counts/min./ml. for whole blood and 10 counts/min./mg for specific activity.

7746 EFFECT OF SODIUM DEHYDROCHOLATE ON THE INTESTINAL ABSORPTION OF BILIRUBI IN THE RAT. (Ger.) Lücking, T. (U. Child. Cli Freiburg i. Br., Germany) and W. Künzer. Klin. Wschr. 45(10):547-548, 1967.

The absorption of bilirubin from the small intestine was tested by intraduodenal inj. of 250 mg/kg of bilirubin dissolved in 0.1 N Na_2CO_3 or suspended in distilled water in white rats (160 No appreciable absorption occurred. This was also true when the bilirubin was dissolved in 1 or 32 mM Na-dehydrocholate. Beginning with a conc. of 64 mM Na-dehydrocholate as a solvent for the bilirubin and continuing through increa ing conc. of the bile salt (128, 256, and 512 m the rate of absorption increased with increased Na-dehydrocholate conc. This was proved by dete mining the serum conc. 1 and 3 hr. after intradu denal inj. of bilirubin. After 1 hr. serum bilirubin at 64 mM bile salt conc. was 0.2 mg, 0.5 mg% at 128 mM, 0.8 mg% at 256 mM, and 1.5 mg% at 512 mM. The effect at 3 hr. was similar, but serum conc. was less. The same experimental sequence was repeated in 2-3-wk.-old rats (18 g) In no case, with or without bile salt, was there any absorption of bilirubin from the small intestine in the young rats. Na-dehydrocholate in higher conc. than 512 mM had no effect.

7747 METHODS FOR THE STUDY OF ABSORPTIVE PATHWAYS IN THE INTESTINE OF CONSCIOUS ANIMALS. (Ger.) Aziz, O. (Free U., Berlin-Dahl Germany), R. Herzer and F. J. Haberich. Naturwissenschaften 54(7):172-173, 1967.

A method is described for the study of absorptio in the intestine of the conscious animal, obviat the unphysiologic conditions presented by the Thiry-Vella, Cori and Pavlov preparations. This method consists in isolating a sufficiently long section of intestine by special clamps and perfusing the section through input and output

as introduced through the intestinal wall.
the end of the test the clamps and the can-
can be removed and the normal passageway
ed. The clamps consist of cuffs of silicone-
tubing which can be filled and pumped up
water through a side tube from the outside;
lamping is smooth, uniform and precise and
e applied without interrupting the blood
The perfusing fluid flows into a graduated
and is then recirculated through the intes-
by means of a peristaltic pump. Samples
e withdrawn from a conveniently-located
e. Vol. changes in the system can be meas-
altered and adjusted. The vol. flow can
asured and adjusted. A graph is presented
ng vol. changes in the perfusion system in
nse to perfusion of the intestinal section
2 hypertonic, 1 isotonic, and 2 hypotonic
, singly 1 after another; all showed very
y rectilinear relationships with flow from
lood to the intestinal lumen in the first
most a net zero vol. flow in the case of
sotonic soln. and a flow from the intestinal
into the blood stream for the hypotonic
The soln. were, 1.8, 1.2, 0.9, 0.45% NaCl
ater.

STUDIES ON THE ABSORPTION AND UTILIZATION OF VARIOUS DIETARY PROTEINS.
9. (Ger.) Miller, B. (U. Marburg/Lahn,
ny), H. G. Knauff and G. Mayer. Verh.
ch. Ges. Inn. Med. 72:703-706, 1967.

a 12-hr. fast the subjects were each given
rotein/kg body wt., consisting (for a person
kg) of 350 g of veal, 420 g of fish or
of powdered milk; meat and fish were grilled
eir own juices and eaten with no other ad-
n than vegetables and 10 g of fat. The
red milk was taken suspended in water. Some
acids (aspartic acid, histidine, leucine,
e, methionine, phenylalanine, serine, threo-
and valine) were present in about the same
ities in the food proteins investigated;
amino acids show considerable differences
roteins of meat, fish and milk. However,
factors also modify the rates at which amino
appear in the peripheral blood plasma, e.g.
e conc., rate of absorption of the amino
and the absorption and rate of utilization
ecific amino acids by cells of the body in
ral and also cells of some organs. Most
acids showed an increase of 100% with a
after 3 hr. The fasting conc. was not
ed until after 4-5 hr. The peripheral peaks
glycine for meat, fish and milk all reached
max. in about 2 hr., between 2-3 hr. for
sine, in about 2 hr. for taurine and in 3 hr.
arginine of meat and fish but not until
4 hr. for arginine of milk. Total α-amino
nitrogen for the 3 proteins reached a max.
hr. in normal subjects. In subjects with
cirrhosis the total α-amino nitrogen
ed about half the normal peak value at 4 hr.
the conc. still rising. The reasons for
total α-nitrogen differences are unknown. The
e of individual differences was large.

7749 THE INTESTINAL ABSOPPTION OF PIG AND BOVINE IMMUNE LACTOGLOBULIN AND HUMAN SERUM ALBUMIN BY THE NEW-BORN PIG. (E.) Pierce, A. E. (A.R.C. Inst. Animal Physiol. Babraham, Cambridge, England) and M. W. Smith. J. Physiol. (London) 190(1):1-18, 1967.

A quantitative immunodiffusion assay was made of protein absorption in newborn pigs to determine the immune globulins absorbed. Large amounts of homologous and heterologous colostral immune globulins and human serum albumin were fed to newborn pigs; these proteins appeared in the serum in low conc. 45 min. later, then rose rapidly to a high level. When equal amounts were fed, no difference was seen between the amounts absorbed, although there was a wide variation among individual pigs. Admin. of equal conc. of pig and bovine colostral IgG resulted in greater pig IgG absorption than bovine. Human serum albumin was readily absorbed from bovine colostral IgG in bovine colostrum. The pig intestine absorbed bovine colostral IgG in proportion to dosage and/or conc. fed, but remained constant for higher doses. A portion of the absorbed immune globulin existed in a partly degraded form. The digestion of protein and individual pig differences made the results unclear to the investigators. Digestion was extensive, 90% of the initially fed protein never being accounted for. It is suggested that the delay in appearance of ingested protein in the serum when low conc. were fed might mean that an increase in protein conc. in the intestine is needed to initiate pinocytosis.

7750 THE IN VITRO TRANSFER OF BOVINE IMMUNE LACTOGLOBULIN ACROSS THE INTESTINE OF NEW-BORN PIGS. (E.) Pierce, A. E. (A.R.C. Inst. Animal Physiol., Babraham, Cambridge, England) and M. W. Smith. J. Physiol. (London) 190(1):19-34, 1967.

Intestinal segments of newborn pigs were either incubated in, or removed after oral admin. of, bovine colostrum containing a known conc. of immune globulin, some of it dialyzed against bicarbonate saline. The intestine was everted into sacs in order to study protein-transfer mechanisms. Large vol. of protein soln. were presented simultaneously to different parts of the small intestine. Stable conditions were maintained through the incubation. Control experiments were designed to establish the viability of the sacs during a 2-hr. period of incubation. Positive serosal transfer of glucose occurred along the whole length of the small intestine (i.e., all segments prepared from it), with a max. transfer of approx. 60 μmole/g/hr. in the jejunum region. Fluid transfer was held fairly constant until the extreme end of the ileum where transfer was approx. halved, thus showing that transfer of glucose and fluid was not quantitatively related. Transmural potentials were present, with the serosal side positive to the mucosal side. In some cases the IgG molecule appeared to have undergone change in its passage through the intestinal wall. Only for some segments did the total transfer depend upon the amount initially fed. The site of max. transfer varied with the conc. of protein fed. Quantitative IgG transfer was greater for colostrum dialyzed against bicarbonate saline than for undialyzed colostrum. In some segments, the presence of albumin lowered serosal transfer of colostral IgG to values approx. those obtained with undialyzed colostrum. The greatest transfer of human serum albumin occurred in the region of greatest inhibition of immune protein transfer by albumin. Histologic and physicochemical evidence suggest that in vitro preparation can survive incubation. Tiny amounts of immune globulin were transferred in vitro approx. 50 times less than when colostrum was first fed to the pig. More protein transferred in the middle-third of the small intestine where albumin-inhibited ion was also greatest. More than 20 albumin molecules transferred for each molecule of immune globulin. Human serum albumin interfered with IgG transfer. The mechanism of protein transfer in these experiments has shown itself to be capable of differentiating between various proteins. More evidence is needed for understanding selectivity and interference among proteins of varying sizes.

7751 DIFFERENTIAL ABSORPTION OF THE HEME AND GLOBIN MOIETIES OF HEMOGLOBIN. (E.) Tripathy, K. (Valle U., Cali, Colombia), F. T. Garcia, L. G. Mayoral, S. Klahr and J. Ghitis. Amer. J. Dig. Dis. 12(6):577-581, 1967.

Four healthy male medical-student volunteers were placed on a basal diet consisting of 3360 calories, with 65 g protein (30 g of animal origin), 140 g of fat and 360 g of carbohydrate as part of a 9-day study. Samples of blood were withdrawn from each subject, the plasma discarded and the RBC analyzed for hemoglobin and total N conc. On the seventh day of the experiment, each subject ingested his own blood mixed with food. In all subjects, there were similar degrees of high fecal excretion of heme pigment with lower excretion of fecal N, concomitant with high excretions of urinary N and creatinine during the 24 hr. after ingestion of blood. While the per cent excretion of heme varied from 50-81% (mean 68%), the per cent excretion of globin was between 3-30% (mean 12.8%). There was an increase in urinary creatinine in all subjects during the 24 hr. after ingestion of blood. These results suggest that the role of blood loss in the pathogenesis of protein malnutrition in patients with hookworm disease is minimal.

7752 HUMAN ABSORPTION OF HEMOGLOBIN-IRON. (E.) Conrad, M. E. (Walter Reed Army Inst. Res., Washington, D. C.), B. I. Benjamin, H. L. Williams and A. L. Foy. Gastroenterology 53(1):5-10, 1967.

Normal volunteers (3) and cirrhotics (3) with patent portacaval shunts were admin. p.o. dose of hemoglobin (0.7 g) labeled with both 10 μc of ^{59}Fe and 40 μc of ^{51}Cr. Jejunal aspirates, obtained 1.5 hr. later, contained significant quantities of dialyzable heme (12-19%) and sma amounts of nonheme Fe (2%). Duodenal biopsy specimens obtained 90 min. after ingestion of the test dose contained both heme and nonheme ^{59}Fe. Plasma specimens contained only nonheme ^{59}Fe. Observations in cirrhotics showed that the absence of labeled heme in plasma specimen was not caused by rapid sequestration in the liver. More Fe was absorbed from test doses o hemoglobin than from comparable quantities of chemically prepared heme. It is thought that degraded globin increases absorption by bindin coordinating bonds of heme and preventing polymerization. Addition of niacin to test doses of heme decreased polymeric aggregation of hem and increased the absorption of heme-Fe. From these results it was concluded that hemoglobin is absorbed by human subjects selectively depe ing upon body requirements for Fe. Heme is sp from globin within the intestinal lumen and ab sorbed into the duodenal mucosa as an intact metalloporphyrin. Fe is split from heme withi intestinal cells and transferred into the plasn Comparison of human and animal studies suggest that the selective absorption of heme-Fe is regulated either by controlled release of Fe from heme within intestinal cells or by regulation of the quantity of Fe transferred from intestinal cells into the plasma or both.

7753 INFLUENCE OF A FAT-ENRICHED MEAL ON HUMAN SERUM (L-PHENYLALANINE-SENSITI "INTESTINAL" ALKALINE PHOSPHATASE. (E.) Ingl N. I. (Tufts U. Sch. Med., Boston, Mass.), M. Krant and W. H. Fishman. Proc. Soc. Exp. Biol Med. 124(3):699-702, 1967.

Normal subjects (8) were given 1 of 2 standard breakfasts after 11 hr. fasting. Breakfast 1 contained 491 calories, 27.3 g fat, 48.2 g carbohydrate and 13 g protein. Breakfast 2 co tained 1002 calories, 696 g fat, 87.5 g carboh drate, and 6.5 g protein. The meal was ingest 15 min. after a blood specimen was drawn, additional blood samples were taken 1 and 4 hr. la In 2 of 4 subjects eating Breakfast 1, a trans increase of L-phenylalanine-sensitive "intesti alkaline phosphatase isoenzyme appeared in the serum. In 4 of 4 subjects eating Breakfast 2, the rise in the isoenzyme appeared and persist for 4 hr. Individuals differed greatly in the pattern of serum enzyme partition which was exhibited. It is concluded that the elevated to alkaline phosphatase is explained by increment in intestinal alkaline phosphatase, especially in subjects eating Breakfast 2 and this findin is attributed to absorption of fat from the intestine. The individual differences in patter may be related to genetic factors as suggested by ABO blood group studies reported earlier.

INTESTINAL TRANSPORT OF CYSTINE AND
CYSTEINE IN MAN: EVIDENCE FOR SEPARATE
NISMS. (E.) Rosenberg, L. E. (Yale U. Sch.
New Haven, Conn.), J. C. Crawhall and S.
. J. Clin. Invest. 46(1):30-34, 1967.

al of 25 biopsies of jejunal mucosa were
ned with a Rubin tube from 5 normal subjects
patients with documented cystinuria. Each
nuria patient excreted excesses of cystine,
e, arginine, and ornithine in the urine and
ormed renal calculi composed of cystine. The
tinal mucosal specimens were placed in flasks
ining either L-cystine-^{35}S or L-cysteine-^{35}S
ncubated. Transport was determined using
ously described technics. Cystine and
ine were transported by energy-dependent,
ted processes. When either of these amino
was transported, only cysteine was recovered
cellularly, indicating that cystine was re-
to cysteine after achieving an intracellular
ion. In contrast to the findings with
ne, cysteine uptake was not defective in
tine from cystinuric patients, nor did lysine
rginine compete with cysteine for transport.
concluded that cystine and cysteine are
sported by different mechanisms and that only
ystine transport mechanism is defective in
nuria.

INTESTINAL ABSORPTION OF ESSENTIAL
AMINO ACIDS IN MAN. (E.) Adibi, S. A.
sachusetts Inst. Techn., Cambridge) and S. J.
. Gastroenterology 52(5):837-845, 1967.

relative rates and preferential absorption
he 8 essential L-amino acids in the lumen
he human intestine were found as a result of
r admin. in the aggregate form in which these
o acids reach the transport sites of the
r jejunum. Eighteen young adults received
molar mixtures by perfusion at conc. of from
mM and in amounts usually found in a protein
. The *in vivo* perfusion of grouped essential
o acids in man had not been reported prior
his study. The importance of such a deter-
tion is confirmed by the fact that these amino
s assign the nutritive value of a protein and
a fundamental role in human protein metab-
m. The literature reports that each amino
admin. separately is transported at a
acteristic rate, but that this rate may be
red by the presence of other amino acids, sug-
ing competition for the transport site. In
present study the rates of absorption of the
ntial amino acids from the equimolar mixtures
not significantly different until conc. of
were reached. Upward of this conc. the diver-
ce in absorption rates became more pronounced,
gesting an abundance of unoccupied transport
es at the lower conc. A characteristic se-
nce and order of amino acid absorption from
mixture was observed which held constant
each of the constituent amino acids. The
orption rates were most rapid for methionine
the branched amino acids, slowest for
threonine. The intestinal juice of the upper jejunum in the fasting state and after perfusion with isotonic saline contains small amounts of amino acids, leucine and lysine predominating. It is concluded that, in the aggregate, amino acids may inhibit the absorption of others if a common transport system exists. For instance, the absorption rate of threonine perfused in an equimolar mixture containing the other essential amino acids was markedly decreased compared to its absorption rate when perfused alone in identical conc.

7756 THE USE OF THE LOGARITHMIC TRANSFORMATION IN THE CALCULATION OF THE TRANSPORT PARAMETERS OF A SYSTEM THAT OBEYS MICHAELIS-MENTEN KINETICS. (E.) Barber, H. E. (U. Michigan, Ann Arbor), B. L. Welch and D. Mackay. Biochem. J. 103(1):251-255, 1967.

A logarithmic method is described for the calculation of the transport parameters, Michaelis constant (K_m) and the max. initial rate of transport at high substrate conc. ($V_{max.}$), of a biological system obeying Michaelis-Menten kinetics. This logarithmic method allowed the estimation of transport parameters that apparently had not been used previously, allowing separation of variance due to $V_{max.}$ from other variance reducing the fiducial limits that can be placed on an estimation of K_m. The velocity of transport of L-histidine and L-monoiodohistidine at various substrate conc. was studied across the small intestine of cats by using an open sac method based on that described by Crane and Wilson. Estimate of the parameters were made by 2 alternative procedures as well as by the new method. It is concluded that the logarithmic method is generally applicable to systems obeying Michaelis-Menten kinetics. This method is particularly useful when transport rates are measured on different pieces of tissue, since $V_{max.}$ may then be the major source of variance.

7757 RECOVERY, REPRODUCIBILITY, AND USEFULNESS OF POLYETHYLENE GLYCOL, IODINE-LABELLED ROSE BENGAL, SULPHOBROMOPHTHALEIN, AND INDOCYANINE GREEN AS NON-ABSORBABLE MARKERS. (E.) Maddrey, W. C. (Johns Hopkins U. Sch. Med., Baltimore, Md.), H. A. Serebro, H. Marcus and F. L. Iber. Gut 8(2):169-171, 1967.

Nonabsorbable reference markers are needed in investigations of gastrointestinal absorption either to estimate the fluid content of the intestine or to compare the conc. of the markers to that of an unknown. The characteristics of an ideal marker were outlined by Smyth (1961): it can be estimated simply and accurately; it can be estimated in small conc. so that its presence will cause the minimum osmotic disturbance, and it should neither be absorbed from the intestine nor be adherent to protein or mucus. Four mongrel dogs were prepared with Thiry-Vella loops utilizing a 30-cm loop of jejunum together with 4 different markers. Quantitative recovery can be made of all these markers from the intact intestinal loop. Only indocyanine green was recovered incompletely, apparently because it is bound to mucus and therefore its usefulness as a marker was diminished. Over a period of 70 min., sampling of the markers remained valid and their experimental use was reproducible from day to day and from animal to animal. Rose bengal and polyethylene glycol emerged best from these studies, demonstrating complete recovery and low variability. The 2 correlate with one another better than any other pair. Rose bengal produced a smaller effect than polyethylene glycol, and was much easier to analyze.

7758 STUDIES ON THE PERMEABILITY BARRIER TO AMINO-ACID PENETRATION OF THE INTESTINAL MUCOSA DURING INCUBATION _IN VITRO_ IN A Na^+-FREE BUFFER. (E.) Schlenker, J. D. (U. Frankfurt, Germany) and J. W. L. Robinson. _Pflueger_. _Arch_. _Ges_. _Physiol_. 294(2):169-181, 1967.

After incubation of rat intestinal slices _in vitro_ in a soln. of (^{14}C)-L-phenylalanine in Na-free, K-substituted buffer (even of long duration), the mean tissue conc. of the substrate never attained the level of the surrounding medium. The amino acid uptake under such conditions kinetically resembled free diffusion, and was directly proportional to the conc. of the substrate in the incubation medium. It is suggested that there exists a kinetic barrier against the penetration of the amino acid into the mucosal cells of the intestine under such conditions, since the results could not be explained in terms of changes in water content of the tissue during the course of incubation. Existence of this barrier requires intact cellular metabolism, since it was destroyed under anaerobic conditions. When choline instead of K ions were used to substitute for Na, there no longer was a barrier against amino acid entry into the mucosa, but no active transport of L-phenylalanine could take place. By preincubating tissue samples in Na-containing buffer and subsequently incubating them in a Na-free, K-rich, phenylalanine-containing buffer, a transient entry of the substrate into the mucosal tissue was observed; the amino acid later left the tissue again. This finding was attributed to Na ions trapped in the extracellular space close to the mechanisms responsible for amino acid uptake by the epithelial cells, which were able to activate the carrier to permit it to transport the amino acid into the cells. However, when the Na ion conc. within the cells exceeded that of the medium (later in the incubation), Na and amino acid left the cells simultaneously by reversal of the uptake mechanism.

7759 THE LOSS OF INTESTINAL TRANSPORT CAPACITY FOLLOWING PREINCUBATION IN SODIUM-FREE MEDIA _IN VITRO_. (E.) Robinson, J. W. L. (U. Frankfurt, Germany). _Pfleuger_. _Arch_. _Ges_. _Physiol_. 294(2):182-200, 1967.

Preincubation of excised rings of rat intesti in Na-free buffer for 30 min. destroyed the ca ity of the tissue to absorb (^{14}C)-L-phenylala against a conc. gradient during a subsequent cubation in the presence of Na ions. Use of Li or Tris ions as substitutes for Na caused plete loss of transport capacity, but use of choline ions was somewhat less damaging. Pre cubation in a 1:1 mixture of Krebs buffer and Na-free, K-substituted buffer also induced a duction in subsequent transport capacity. The results could not be assigned to lack of metab lizable substrate within the cells when Na was absent from the preincubation medium. They we best explained by suggesting that the Na pump, which is intimately linked with amino acid accumulation within the epithelial cells, was de stroyed during the preincubation period. Then when the tissue was replaced in a Na-containin soln., the cells were flooded with these ions, which may then have been responsible for destr tion of the characteristic properties of the c membrane. Permeation of the tissue with radio active Na after a preincubation in K-rich medi was significantly greater than in control samp as was the penetration of mannitol. This loss of activity after preincubation in the absence of Na ions was partly species-specific; it was present in the rat and the mouse, and absent f the rabbit intestine. (According to the liter it was also absent from the toad and the hamst Since the species from which the effect was absent have intestines possessing ouabain-sens. Na pumps that are involved in non-electrolyte transport, it is suggested that this correlati between sensitivity to Na-free preincubation ar lack of susceptibility to ouabain provides furt evidence for qualitative differences between th Na-pump mechanisms in different animal species.

7760 INTESTINAL TRANSPORT OF SODIUM, POTAS SIUM, AND WATER IN THE DOG DURING SODIUM DEPLETION. (E.) Clarke, A. M. (Western Infirm., Glasgow, Scotland), M. Miller and R. Shields. _Gastroenterology_ 52(5):846-858, 1967.

The absorption of electrolytes from the gut is evidently not as uncontrolled and indiscriminat as has been supposed. The unidirectional trans port of Na, K and water in isolated segments of dog ileum, jejunum and colon were studied befor during and after Na depletion. During depletio the absorption of Na and water, as well as the secretion of K, was seen to increase, particula in the ileum and colon. These changes in the net transport of Na and K were accompanied by appropriate alterations in the rates at which these ions entered the intestinal lumen. Water absorption was increased when the animal was depleted of Na but no marked constant alteration in its unidirectional flow was observed. The intestinal tract did not respond uniformly to Na depletion: absorption of water by the ile and colon was increased during salt depletion whereas in the jejunum there was no detectable alteration. Contrasting with the invariable

se in the secretion of K in the ileum and
the effect of salt depletion upon the
secretion of K was inconsistent. The
segments absorbed Na and water more
than the more distal segments, a phenomenon
both control experiments and during salt
ion. Alterations in intestinal absorption
ctrolytes during Na depletion resembled
resulting from aldosterone admin. Such ef-
could not be blocked by the prior admin. of
olactone. This failure was attributed to
obable high production of aldosterone by
renal cortex of the stressed animal.

ABSORPTION OF VITAMIN B_{12} FROM THE SMALL INTESTINE. STUDY IN MAN, MONKEY, CAT,

G. (E.) Gazet, J. C. (Guy's Hosp.,
) and I. McColl. Brit. J. Surg. 54(2):128-
967.

tion was studied (in surgical patients,
s, cats, dogs) by a modification of the
of McColl and Nissim: at laparotomy a
f proximal jejunum and a loop of distal
were emptied by digital pressure and isolated
oncrushing intestinal clamps; 50-100 ml
saline (37°) was inj. through the wall
he lumen; the loops were reemptied and the
g repeated; to give surface areas of 150
qual lengths of jejunum and ileum, corrected
dth, were measured and clamped off; into
solated and washed intestinal segment a
vol. of 37° normal saline with varying
of radioactive vitamin B_{12} was inj.; either
or ^{58}Co-vitamin B_{12} (specific activity
μc/μg) or ^{22}NaCl (0.1 μc/ml) was used in
of 0.0002-0.011 μg/ml soln., giving 10-
s/5 ml; soln. were withdrawn after 15 min.,
easured, and radioactivity counted. In 3
nd 5 monkeys, the rate of absorption of
nd ^{22}Na was approx. linear over 1 hr., in
he jejunum and ileum. As the percentage
tion of vitamin B_{12} did not increase after
rst 15-min. reading, this period of time
ed for subsequent studies. In a total of
gments studied in 20 patients, 10 monkeys,
, and 36 dogs, little difference was found
n the absorption ability of the jejunum
eum. In humans and cats, the jejunum ab-
more vitamin B_{12} than did the ileum. Ab-
on here was concluded to involve active
ort. There was no statistically significant
rence between jejunum and ileum in the
monkey and dog. These results do not sup-
he contention that vitamin B_{12} can only
sorbed by the ileum by an exclusive mechanism.

BIOSYNTHESIS OF RETINOIC ACID BY INTESTINAL ENZYMES OF THE RAT. (E.)

, F. D. (West Virginia U. Sch. Med.,
ntown), F. J. Lotspeich and R. F. Krause.
pid Res. 8(3):249-254, 1967.

ncubation of β-carotene-^{14}C with the soluble
ion of the intestinal mucosa resulted in
ormation of small amounts of acidic material.
The addition of nicotinamide adenine dinucleotide or reduced nicotinamide adenine dinucleotide to the soluble fraction caused a tenfold increase in this material. Incubation of retinal-15-^{14}C with the soluble fraction of the intestinal mucosa plus nicotinamide adenine dinucleotide or reduced nicotinamide adenine dinucleotide resulted in the conversion of 80-90% of the retinal to acidic material, which has been shown to contain retinoic acid. In vivo studies on the formation of retinoic acid in the intestinal mucosa after the admin. of β-carotene-^{14}C revealed that an appreciable amount of β-carotene was converted to acidic compounds. When retinal-15-^{14}C was admin., portal blood contained 30-40% of the absorbed radioactivity; 24% of this radioactivity was found in acidic material, which has been shown to contain retinoic acid. It is suggested that enzymes in rat intestine cleave β-carotene to retinal and oxidize the latter to retinoic acid, which is then transported by the portal circulation to the liver.

7763 STUDIES ON INTESTINAL ABSORPTION OF CALCIUM AND STRONTIUM IN THE RAT.

(Ger.) Pany, J. E. (U. Vienna). Wien. Klin. Wschr. 79(24):489-492, 1967.

Rats (120-150 g) were anesthetized and an intestinal loop, retaining its normal vascular supply, was constructed; there was only 1 loop/rat, either duodenal-jejunal, 10-12 cm long immediately below the duodenum; the ends of the loop were cannulated and connected in a series circuit having a pump of constant min. vol. output and a reservoir for the perfusate, warmed to 37°C; the open ends from the stomach and to the intestine in situ were tied off. The loop was first perfused with 20 ml of Ringer's soln., then with 20 ml of the test soln. for 1 hr.; the vol. used was always 20 ml and the time of perfusion 1 hr. The test soln. were isotonic bicarbonate Krebs-Ringer's radioactively labeled with 2 μc $^{45}CaCl_2$ or 2 μc $^{90}SrCl_2$; these soln. were used directly or with increased Ca content in the form of an added 300 mg Ca gluconate (28.7 mg Ca) or 200 mg Ca lactate (32.6 mg Ca). In all cases the radioactivity was measured before and after perfusion in a gas flow counting system. After ashing, the radioactivity of the tissue of the loop was measured as activity/mg of ashed tissue. Activity of the blood/100 g of body wt. was also established. Activities of ashed tissue and then of blood perfusing the loop were as follows: with normal Ringer's duodenum 226 (ashed) and 534 (blood), jejunum 1890 (ashed) and 319 (blood); with Ca gluconate duodenum 146 (ashed) and 125 (blood), jejunum 411 (ashed) and 171 (blood); with Ca lactate duodenum 166 (ashed) and 151 (blood), jejunum 667 (ashed) and 151 (blood). The chief effect was the inhibition of absorption apparently due to the gluconate and lactate groups, especially the former. These experiments repeated with radioactive Sr showed the same type of inhibition in a more uniform and pronounced degree. The results from the duodenal loops cannot be compared to those from the jejunal loops because of unspecified differences in length. Moreover, addition of more Ca as lactate or gluconate must have a diluting effect upon the radioactive Ca, as well as an effect upon permeability of the cell.

7764 CYTOCHEMICAL LOCALIZATION OF SOME GLYCOSIDASES AND OTHER ACID HYDROLASES IN THE ABSORPTIVE EPITHELIUM OF THE HUMAN SMALL INTESTINE. (Ger.) Riecken, E. O. (Med. U. Clin., Marburg, Germany), H. A. Schmidt, K. Wächtler and A. G. E. Pearse. *Klin. Wschr.* 45(7):383-387, 1967.

Fresh biopsy tissue was obtained from the mucosa of the jejunum 15 cm below the ligament of Treitz under radiologic control. The tissue was immediately fixed for 12 hr. in formalin-calcium at 4°C, washed in ice cold gum arabic-sugar soln., and finally frozen in liquid nitrogen. Fresh liver tissue and, in some cases, the very enzymatically-active intestine of the snail, *Patella vulgata*, served as control material. The enzymes were identified by well-established technics and the use of precise conc. of inhibitory compounds (such as 5×10^{-2} M phenylalanine on acid phosphatases). The enzymes demonstrated were 1) nonspecific acid phosphatases; 2) nonspecific lysosomal esterases; 3) arylsulfatase C; 4) β-D-glucuronidase; 5) β-D-glucosaminidase; 6) α-D-glucosidase; 7) β-D-galactosidase. Heated sections without substrate were used for technic control. Sections were prepared for the optical microscope and also for the ultramicroscope for fine structural localization of enzymes with a combined histochemical and ultramicroscopic method. The unspecific acid phosphatases, E600-resistant esterase, β-glucuronidase and β-glucosaminidase demonstrated the same localization in human intestinal mucosa and control tissues but with differences in intensity. They were restricted to a narrow zone of granular particles which lay below the brush border. The brush border itself was stained only in the acid phosphatase reaction, and then only lightly. Arylsulfatase C was not demonstrable in human tissue; some weak arylsulfatase C showed up in human macrophages. The cytochemical-ultramicroscopic combined method placed the nonspecific acid phosphatases in the lysosomes. α-Glucosidase and β-galactosidase could not be demonstrated in human tissue on a cytochemical level.

7765 KINETIC STUDY OF THE MODIFICATIONS IN THE ELECTRIC ACTIVITY OF THE SMALL INTESTINE OF THE RAT DURING ABSORPTION OF SUGARS. (Fr.) Rougereau, A. (Fac. Med., Tours, France), C. Janvier and J. Thouvenot. *C. R. Soc. Biol. (Paris)* 160(11):2183-2187, 1966.

The electrical activity of the intestine was recorded using a unipolar suction electrode attached to an intestinal loop (15-cm) long) through which a regular flow of 4.5 ml/hr. of sugar (or other) soln. warmed to 36°C, was maintained by a fractionating pump. The rate of absorption of these compounds, continuously monitored over a period of at least 1 hr. by mear of an autoanalyzer, was correlated with the electrical activity simultaneously recorded. In addition to 22 tests on glucose, the following multiple tests were made on galactose (6), ribose (3), mannose (3), arabinose (3) and sucrose (3), as well as other multiple tests on ATP alone and ATP in conjunction with glucose, ribose, mannose, and xylose; fructose-6-phosphate was tried. A number of different metabolic inhibitors, monoiod acetic acid, 2,4-dinitrophenol, sodium fluoride, phlorhizin, and sodium azide, alone and with glucose, were investigated. The electrical values were given as percentages of the time on the recording; high electrical readings correlate with the high rates of absorption; thus the overall electrical values for galactose and glucose are given as 10.6 and 10, resp., the highest among the sugars; of those tested, these 2 sugars had the most rapid rates of absorption whereas sucrose with no absorption had no electrical response. The electrical variations which were recorded were due to the action currents of smoot muscle. This indicates that the degree of muscular activity influences the rate of absorption. The electrical value of ATP alone was 16.5 ATP and glucose had a value of 12, 2 greater than for glucose alone; the values for other sugars were also increased; the rates of absorption were proportionately increased. In the presence of metabolic inhibitors the electrical values for glucose were abolished in 2 instances and much reduced (to 18% or less) in 3, as were the rates of absorption.

7766 INTERPRETATION OF HEXOSE-DEPENDENT ELECTRICAL POTENTIAL DIFFERENCES IN SMALL INTESTINE. (E.) Schultz, S. G. (Harvard Med. Sch., Boston, Mass.), P. F. Curran and E. M. Wright. *Nature (London)* 214(5087):509-510, 1967.

It is demonstrated mathematically that the hexose dependent increase in the I_{sc} (the short circuit current across the mucosal surface of small intestine) is a function of Na conc. and that the observed differences in the hexose-dependent potential difference in the presence of mannitol, tris(2-amino-2-hydroxymethyl-1,3-propanediol) on K can be attributed, at least partially, to differences in tissue conductance.

7767 INHIBITION OF INTESTINAL SUGAR TRANSPORT BY PHENOLPHTHALEIN. (E.) Adamič, Š. (U. Manitoba, Winnipeg, Canada) and I. Bihler. *Molec. Pharmacol.* 3(2):188-194, 1967.

The Na-dependent active transport across segments of the small intestine of the hamster, of 3-methy D-glucose, a nonmetabolized glucose analog, was competitively inhibited by phenolphthalein *in vitro*. When sugar accumulation against a conc difference was prevented by metabolic inhibitors or by replacing Na in the bathing medium with Li, phenolphthalein inhibited the specific ion-activated sugar entry process; this is interpreted as

ct inhibition of the sugar carrier. Phenol-
alein was extensively bound to tissue protein,
it could not be determined whether it was
lf transported across the cell membrane.
olphthalein inhibited the Na-dependent in-
inal active transport of α-aminoisobutyric
as well as its entry in the presence of
bolic inhibitors or in Li medium; this suggests
raction with the amino acid carrier. It is
luded that phenolphthalein affects intestinal
r transport by competitively inhibiting the
r carrier. The data do not show to what
nt inhibition of the sodium pump (demonstrated
thers) may participate in inhibition of
r transport.

ISOLATED PERFUSED RAT SMALL BOWEL--
TECHNIC, STUDIES OF VIABILITY, GLUCOSE
RPTION. (E.) Kavin, H. (U. Witwatersrand
Sch., Johannesburg, South Africa), N. W.
n and M. M. Stanley. J. Appl. Physiol. 22(3):
611, 1967.

r fasting overnight the rats were anesthetized
ether and the small intestine exposed by
rtical incision. The intestine was washed
divided into quarters and cannulae inserted
the free ends of the segments. After ap-
riate arterial and venous isolation the in-
ine was perfused through the aorta and drained
ugh the portal vein. The intestinal segments
left in situ, the rat killed and placed in a
tant temperature and humidity chamber. An
ficial plasma and washed bovine RBC were used
erfusate. Schanker's soln. was used for the
stinal lumen fluid. An initial period of
constriction (10 min.) was noted. Vigorous
staltic waves were not found to be a clear
of a viable preparation but in most instances
gn of some failure in the preparation. O_2
umption was 0.09 ml O_2/min./g dry intestine
and was not found to change appreciably
ng an experiment. Net uptake of glucose was
mg/min./100 mg dry wt. Glucose was trans-
ed against a conc. gradient, despite a net
of water into the lumen from the blood
eam, this occurred to the extent of 0.2-32.9%
he initial water in the lumen. Histologically,
villous pattern appeared normal after 1-2 hr.
fusion. It is concluded the technic has wide
lication in the study of intestinal absorption,
retion and metabolism.

9 ABSORPTION OF GLUCOSE FROM THE SMALL
INTESTINE IN EXPERIMENTAL HYPERTENSION.
s.) Amirov, N. S. (Inst. Normal Pathol.
siol., Acad. Med. Sci., Moscow). Pat. Fiziol.
. Ter. 11(1):75-76, 1967.

erimental hypertension was induced in 8 dogs
the method of Goldblatt (repeated constriction
the renal arteries at a 2-wk. interval); the
mals were divided into 3 groups as follows:
up 1 (3 dogs) isolated intestine removed from
proximal portion of the jejunum; Group 2
(3 dogs) with a jejunal fistula; and Group 3 (2 dogs) with isolated segments of the central part of the small intestine. In Group 1, absorption of glucose (in % of admin. glucose), 30 min. after the admin. of 20 ml of a 10% glucose soln. into the isolated intestine, varied between 20.4-65.3 during hypertension, as compared to 56.4-78.8 in controls; the blood sugar content on a fasting state, studied in 1 of 3 animals, was 72.0 mg% in hypertension and 69.0 mg% in controls. In Group 2, the increase in blood sugar (after admin. of 150 ml of glucose soln.) and blood sugar conc. in the fasting state was 53.5-87.0 mg% and 75.1-91.1 mg%, resp., as compared to 38.2-47.3 mg% and 56.3-79.1 mg%, resp., in controls. A reliable increase in blood sugar conc. in the fasting state was found in only 1 of 3 animals. The percentage of glucose absorption from the isolated intestine in Group 3 was 64.8-71.2 in hypertensive animals, and 34.7-40.5 in controls. Blood sugar content in the fasting state, studied in 1 of 2 animals, was 88.5 in hypertensive animals and 102.5 mg% in controls. Thus, in experimental hypertension, variable changes of glucose absorption were found from different parts of the small intestine. It is the author's opinion that decreased absorption from the proximal portion of the jejunum may be related to disruption in blood supply in this region, and that the increase in absorption from the total intestine may be related to an increased blood supply in the remaining part of the small intestine.

7770 EFFECT OF INTRA-INTESTINAL INJECTION OF INSULIN ON GLYCEMIA. STUDY ON THE RAT. (Fr.) Rougereau, A. (Fac. Med., Tours, France), E. Aron and J. Thouvenot. C. R. Soc. Biol. (Paris) 160(11):2187-2192, 1966.

Glycemia was studied in fasting rats (200-300 g) under artificial respiration and infused via the jugular vein with 0.9% NaCl 3 ml/hr.; the blood of the animal, treated with 0.6 mg of heparin, was taken from the femoral vein or the portal vein by a fine catheter (total 3 ml/hr.). The blood glucose was determined by an autoanalyzer. The soln. of glucose which passed down an intestinal loop of 15-20-cm was recovered at the end of the loop for glucose determination in the autoanalyzer. The flow of these soln. through the lumen of the loop was about 4.5 ml/hr. The intraluminal inj. of insulin only elicited 2 types of action on the initial levels of blood glucose: when the blood glucose was between 70 and 90 mg% intraluminal insulin caused hypoglycemia, but when the blood glucose was more than 90 mg% a slight hyperglycemia resulted. Only doses of insulin greater than 2 I.U. had any effect, which seems to confirm the fact that the rat is relatively insensitive to insulin. Inj. of 8 U into the intestinal lumen caused a drop in blood sugar from 80 mg% to 30 mg% in 30 min. with recovery to 80 mg% in about 90 min. after inj.; this was the course followed in the blood obtained from the femoral vein. Blood taken from the portal vein showed a blood sugar rise to

135 mg% at 40 min. then a fall to 65 mg% at 60 min. Intraluminal inj. of 10 I.U. insulin and phlorhizin 1 x 10^{-3} caused death by aglycemia at 65 min. The preceding tests were all done with 0.9% NaCl in the intestinal loop. When glucose was inj. i.v. (2 g/liter, 2 ml vol.) blood glucose rose from 105 mg% to 235 mg% in 35 min. then began to decline; the same conc. of glucose containing 4 U of insulin showed 42% less of a rise. Using the same conc. of glucose, and glucose and insulin, in the intestinal lumen produced hyperglycemia in the former, but an actual fall in the latter after a 5-min. interval. When the lumen was infused with these same soln. the rise in blood sugar in the portal vein was only about half that with insulin as without it; with insulin the slope was less but continued rising for a longer period, about 75 as compared to 40 min.

7771 TRANSPORT OF THIAMINE-^{14}C IN RAT INTESTINE, *IN VITRO*. I. RELATIONSHIP BETWEEN PHOSPHORYLATION OF THIAMINE AND ITS TRANSPORT AGAINST THE CONCENTRATION GRADIENT. (It.) Rindi, G. (U. Ferrara, Italy) and U. Ventura. *Boll*. *Soc*. *Ital*. *Biol*. *Sper*. 42(24):1974-1977, 1966.

In 8-cm sections of rat small intestine, derived from Wistar-strain animals weighing 120-150 g and incubated with ^{14}C-labeled thiamine (thiazole-2-^{14}C at 0.1 mc/1.26 mg) in Krebs-Henseleit soln. for 1 hr. at 37°C, the conc. of radioactive thiamine phosphate in the intestinal wall (n-moles/500 mg wet tissue) was approx. double the conc. of radioactive, nonphosphorylated thiamine in the serosal fluid (also expressed as n-moles/500 mg wet tissue), even though the conc. in serosal fluid had increased by 2.5-3.0 times. When inhibitors of cellular metabolism were added to the incubation liquid, both the conc. of thiamine in serosal fluid and the conc. of thiamine phosphate in parietal tissue were reduced sharply. In the absence of such inhibitors, the increase of thiamine conc. in serosal fluid was uniform and progressive throughout the 1-hr. observation period; that of intraparietal thiamine phosphate peaked within 20-25 min., with no significant increase thereafter. It is concluded that *in vitro* transport of thiamine in the rat intestine does not parallel the gradient of conc. in serosal fluid, but is linked directly to the phosphorylation activity of the intestinal mucosa. (See also GAC #7772 and #7773.)

7772 TRANSPORT OF THIAMINE-^{14}C IN RAT INTESTINE, *IN VITRO*. II. EFFECTS OF CERTAIN STRUCTURAL ANALOGS OF THIAMINE ON ITS TRANSPORT AND PHOSPHORYLATION. (It.) Ventura, U. (U. Ferrara, Italy) and G. Rindi. *Boll*. *Soc*. *Ital*. *Biol*. *Sper*. 42(24):1977-1979, 1966.

In 8-cm sections of rat small intestine, derived from Wistar-strain animals weighing 120-150 g and incubated with ^{14}C-labeled thiamine (0.1 mc/1.26 mg) in Krebs-Henseleit soln. for 1 hr. at 37°C, addition of 2 x 10^{-5} or 2 x 10^{-6} oxythia to the incubation medium failed to affect the progressively increased conc. of thiamine in t serosal fluid, its phosphorylation by the intestinal mucosa, or its subsequent transport (#7771). However, addition of 10^{-6} M pyrithiam 2-ethylthiamine or 2-butylthiamine resulted in marked reduction of both intraparietal thiamin phosphate and the conc. of thiamine in serosal fluid. It is concluded that the phosphorylati of thiamine by the epithelial cells of the rat small intestine (which these last 3 substances inhibit significantly, *in vitro*) is at least o of the mechanisms which regulates *in vitro* intestinal transport of thiamine. (See also: #7773.)

7773 TRANSPORT OF THIAMINE-^{14}C IN RAT INT TINE, *IN VITRO*. III. EFFECT OF INHIBITORS OF INTESTINAL PHOSPHATASE ON THE TRAN PORT AND PHOSPHORYLATION OF THIAMINE. (It.) Ventura, U. (U. Ferrara, Italy), G. Sciorelli M. V. Bonanni. *Boll*. *Soc*. *Ital*. *Biol*. *Sper*. 42(24):1979-1981, 1966.

In 8-cm sections of rat small intestine, deriv from Wistar-strain animals weighing 120-150 g and incubated with ^{14}C-labeled thiamine (0.1 mc/1.26 mg) in Krebs-Henseleit soln. for 1 hr at 37°C, resulting conc. of thiamine in serosa fluid and of thiamine phosphate in the intest wall were reduced significantly by the additio of 10^{-2} M ethylenediaminetetraacetic acid (but not by the addition of 10^{-3} M or 10^{-4} M) to th incubation media. A less marked, but still si nificant, effect was produced by the addition 10^{-4} M Cu ions in the form of $CuSO_4$, but not b the addition of 10^{-5} M. No significant effect were exerted by the addition of 3.1 µg/ml poly phloretin phosphate or 10^{-4} M Be ions in the form of beryllium chloride. However, every diminution of the conc. of thiamine in serosal fluid, whether or not it occurred at a level c statistical significance, was paralleled by a diminution of the intraparietal conc. of thiam phosphate. (See also: #7771, #7772.)

7774 PHOSPHORYLATION AND UPHILL INTESTINA TRANSPORT OF THIAMINE, *IN VITRO*. (E Rindi, G. (U. Ferrara, Italy) and U. Ventura. *Experientia* 23(3):175-176, 1967.

Everted sacs (8-cm long) from the upper small intestine of rats (Wistar strain, 100-150 g) were prepared and incubated for 1 hr. in Krebs Henseleit soln. as previously described. The initial conc. of thiamine HCl (thiazole-2-^{14}C) was 0.2 µM/ml at both sides of the sac, the initial serosal vol. was 1.2 ml. A 0.5 ml sam of serosal fluid was taken after incubation, t sac homogenized and both were appropriately pr pared and counted. Several metabolic inhibit and thiamine analogs were initially added at t sides of the sac. The results indicate that thiamine was phosphorylated during uphill sport, and that inhibition of phosphorylation the metabolic inhibitors or analogs always ced thiamine uphill transport. This suggests phosphorylation is a basic mechanism for mine intestinal transport. That net transport always more inhibited than thiamine phos- ylation suggests that phosphorylation is not sole mechanism involved.

EFFECT OF LIGATION OF THE PANCREATIC DUCT ON THE ABSORPTION OF RADIO IRON ATS. (E.) Murray, M. J. (U. Minnesota, eapolis) and N. Stein. Gastroenterology):38-41, 1967.

t groups of 10 female Sprague-Dawley rats were studied: Group 1, normal animals; p 2, rats with Fe-deficiency anemia; Group 3, als with ligation of the pancreatic duct; p 4, animals with ligation of the pancreatic and parenteral Fe overload; Group 5, animals ligation of the pancreatic duct and anemia; p 6, animals with fatty livers induced by ine deficiency; Group 7, animals with fatty r and parenteral Fe overload; and Group 8, als with ligation of the pancreatic duct fatty liver. Each group was given an p.o. of ^{59}Fe as ferrous citrate and the total activity was measured 14 days later; the vity remaining at the end of 14 days was rded as the percentage absorption of ^{59}Fe. order to compare the immediate effect of liga- of the pancreatic duct (exclusion of secre- from the gut) with long term effects of ation (atrophy of the exocrine gland), 6 als were studied 3 days and 4 wk., resp., r operation; 6 sham-operated animals served controls. There appeared to be no significant ference between the immediate (3 days after ation of the duct) and late (31-48 days after ration) effects of pancreatic duct ligation the uptake of ^{59}Fe. All animals, other than trols, lost wt.; the hemoglobin levels fell in groups except the controls and the Fe-loaded ty liver group. Whereas animals with fatty er, anemia and with anemia plus pancreatic ligation had statistically significant in- ases in absorption, those with isolated pan- atic duct ligation showed decreases which were significant. Mean ^{59}Fe absorption by the mic group at 14 days was 53.5%, which is h greater than that for the anemic group with t ligation (28.9%). Parenteral Fe admin. eared to depress absorption of the fatty liver up and the group with isolated duct ligation n further. Duct ligation superimposed upon ty liver inhibited the increased absorption ected in the fatty liver group.

6 IRON ABSORPTION FROM LIVER IN YOUNG INFANTS. (Ger.) Eichler, I. (U. ld. Clin. Heidelberg, Germany) and K. Schreier. Kinderheilk. 100(1):57-63, 1967.

ants (12) at an av. age of 15 wk., and in good health, each received in the noon feeding on 3 successive days 100 g of finely homogenized calves' liver. The stools were collected and the total Fe determined. Fe was measured in the blood before and after the intake of liver and in the food (milk as well as liver). The av. amount of Fe ingested by each infant during the test period was 48,292 μg; the av. amount in the feces/infant was 16,412 μg; the difference (i.e., the amount absorbed) was 31,880 μg/infant. About 66% of the Fe presented was absorbed. Fe was absorbed twice as readily from liver as from spinach. In infants Fe was better absorbed from meat and liver than from eggs and vegetables. The serum conc. of Fe increased in 3 infants from an av. of 45 μg% to 144 μg% in 2 hr. after the last liver feeding; 22 hr. after the last liver feeding, the Fe conc. were back to their original pre-feeding levels.

7777 GASTRIC FACTORS INFLUENCING IRON ABSORPTION IN ANAEMIC PATIENTS. (E.) Jacobs, A. (Cardiff Roy. Infirm., Wales), J. Rhodes and J. D. Eakins. Scand. J. Haemat. 4(2):105-110, 1967.

Gastric acid secretion was measured by the histamine-infusion method of Lawrie. In normals, a sample of resting juice was aspirated and the pH measured. Fe absorption was measured by the double-isotope technic (tracer dose of 12.5 μc ^{59}Fe in standard meal and 0.7 μc ^{55}Fe i.v., both as ferric citrate, were given simultaneously and RBC isotope activity measured after 14 days). Absorption was measured twice in 9 healthy men (gastric pH 1-2; hemoglobin 14.5-18.6 g/100 ml) and once in 9 women with chronic Fe deficiency anemia due to menstrual loss (hemoglobin 4.9-8.4 g/100 ml). Acid secretion was 0-48 mEq/hr. Just before the first label meal, normals received 200 ml fresh histamine-stimulated gastric juice from Fe-deficient patients. When the vol. of juice was less than 200 ml it was made up with 0.1 N HCl; the second meal was 3 mo. later (150 ml water instead of juice). In anemic patients absorption of ^{55}Fe was 16-80%, higher in normal than in hyposecretors. In controls, absorption was 4-18% (av. 10.3%) without juice, and 0-23% (av. 8.3%) with anemic juice. With anemic juice, absorption was higher in 2, lower in 6. Differences in absorption in 2 tests were not related to gastric acid secretion or absorption level of donor. Seven women with achlorhydria (5 idiopathic Fe-deficiency anemia, 2 untreated pernicious anemia; hemoglobin 5.6-8.1 g/100 ml) received a known vol. of fresh histamine-stimulated juice from normal secretors (6 women, 1 man) with chronic Fe-deficiency anemia, and a standard meal and Fe label were given. RBC radioactivity (14 days) was used to measure absorption and as a baseline for the second test, also that day (150 ml water). Absorption in achlorhydria was 3.8-43% (av. 11.6%). When juice was added to the test meal, absorption increased 1.5-25.1%, and increase was related to secretion of donor. Range of absorption with juice was

5.3-46% (av. 21.9%), a significant increase for the group as a whole. Absorption was also measured in 3 women, with severe Fe-deficiency anemia and complete achlorhydria (hemoglobin 5.5-6.5 g/100 ml), with 200 ml water and 14 days later with 200 ml 0.1 N HCl. Without HCl, absorption was 18-26.1% (av. 20.8%) and with HCl 30.1-43.2% (av. 35.7%), a significant increase in all 3. The findings that absorption of tracer dose in normals did not increase by simultaneous admin. of gastric juice from anemics and that absorption in achlorhydric anemia increased with admin. of anemic gastric juice due to acid content of gastric juice do not support the hypothesis that there is a substance in gastric juice other than acid which influences absorption.

7778 IRON ABSORPTION AND LIVER IRON DEPOSITION IN THE RAT. (E.) Van Wyk, C. P. (Nat. Nutr. Res. Inst., Pretoria, South Africa). S. Afr. Med. J. 41(16):417-421, 1967.

Six basic diets were given to rats, and within each dietary group there were 6 subgroups, differing in amount of Fe. Iron was supplied to Diets 1-4 as Fe citrate, to 5 and 6 as free; metallic Fe. The basic diets were: 1) semi-synthetic "balanced"; 2) maize porridge meal + 3% NaCl; 3) low protein; 4) "balanced" with maize porridge meal as source of carbohydrate; 5) as in 1; 6) as in 2. In the 6 subgroups, Fe added amounted to 4, 99, 193, 288, 384, and 474 mg/g diet, resp. (added at the expense of the dextrin/maize fraction). After 27 days the rats were killed and liver nonhemoglobin Fe content determined (Kaldor). Determination of Fe absorption involved measurement of difference between amount of Fe ingested during the "balance" period of 10 days (8-17) and amount excreted in feces during this period. Fe absorption usually increased with increased intake, but the rate of increase was a function of diet. Rates (in decreasing order) were: Diets 2, 4, 6, 1, 5, 3 (essentially no increase in absorption with Diet 3). There was a generally close relationship between rate of absorption and liver nonhemoglobin Fe content (6, 2, 4, 1, 5, 3). At comparable Fe absorption levels, much more Fe was deposited in the liver when the diet consisted of metallic Fe and maize (5.12 mg/g dry wt. liver in 6) than with either type of Fe with any other diet (3.2 in 2; 2.07 in 4; 1.70 in 1; 1.49 in 5; 0.89 in 3; all with max. Fe). It is concluded that the most important factors in the etiology of experimental siderosis in rats were a combination of certain properties of maize, high Fe intake, and the presence of free, metallic Fe particles in the diet.

7779 GASTRIC IRON BINDING PROTEIN IN IRON CHELATION BY GASTRIC JUICE. (E.) Davis, P. S. (U. Adelaide, Australia), C. G. Luke and D. J. Deller. Nature (London) 214(5093):1126, 1967.

Samples of gastric juice were obtained from 9 fasting normals before, and at 15, 30, 45, and 60 min. after stimulation of gastric secretion by histamine. Fe-chelating ability was assayed with a radioiron solubility test. Resting and histamine-stimulated samples possessed a marked Fe-binding capacity in all subjects examined. The av. amount of Fe-bound/ml gastric juice was 0.04 mg/ml in fasting juice, 0.02 mg/ml in histamine samples. Therefore, sufficient Fe-bi ing substance should be secreted in gastric jui to chelate all the 15 mg of dietary Fe present in a typical diet. Fe-binding ability was also measured by the passage of gastric juice labele with radioiron through a Sephadex G200 column. While the gastric juice was resolved into 3 maj fractions, the radioiron was bound exclusively by the totally excluded high molecular wt. fraction (above 200,000). Elution curves of simila treated samples of albumin and transferrin show that the gastric Fe-binding protein was neither of these. It is unlikely that Fe is present in the intestinal lumen in ionic form to any appreciable degree.

7780 THE PASSAGE OF FERRITIN INTO JEJUNAL EPITHELIAL CELLS. (E.) Casley-Smith J. R. (U. Adelaide, Australia). Experientia 23(5):370-371, 1967.

Adult rats had a loop of jejunum isolated by ligation of its ends, leaving the blood supply intact. One ml of 5% ferritin in physiological saline was inj. into the loop and left for 3 hr Rats were killed and tissues prepared for elect microscopy by standard methods. The epithelial cells at the distal ends of the villi had numerous particles of ferritin between their microvilli. There were occasional small invaginations at the bases of the microvilli; some o these contained ferritin. Small vesicles in th cell also sometimes contained a few molecules o ferritin. They were also present occasionally throughout the cell membrane systems and, extracellularly, at the bases and sides of the cells. The epithelial cells near the proximal end of th villi had much less ferritin adjacent to their small and infrequent microvilli. In these young cells there were many more small invaginations. There were therefore almost as many ferritin molecules in the invaginations and small vesicle in these cells as in the more distal ones. The fact that a small proportion of intact protein molecules can enter adult rat jejunal epithelial cells through the small vesicles, and pass through them into the body, is suggested to be the basis of intestinal allergic phenomena.

7781 CHANGE IN GASTRIC IRON-BINDING PROTEIN (GASTROFERRIN) DURING IRON-DEFICIENCY ANAEMIA. (E.) Luke, C. G. (U. Adelaide, South Australia), P. S. Davis and D. J. Deller. Lancet 1(7496):926-927, 1967.

One author was made anemic and iron-deficient by repeated venesection and removal of 2500 ml

d in 6 days. Fasting gastric juice was col-
ed before, during and after venesection, and
r 8 wk., by which time hemoglobin and serum
evels had returned to normal. In 2 patients
Fe-deficiency anemia from bleeding duodenal
rs, fasting gastric juice was collected before
l wk. after correction of anemia by trans-
on. Fasting gastric juice was obtained only
he Fe-deficient state in 8 with Fe-deficiency
ia due to gastrointestinal hemorrhage or
rrhagia. Juice was obtained after a 12-hr.
through a stomach tube. Fe-chelating ability
amples was measured by a radio Fe-solubility
. Protein components were separated by pass-
on a Sephadex G200 column. Hemoglobin and
n Fe of all patients were measured on several
sions. Fe-binding capacity was decreased in
ia and returned to normal with correction of
ia. Vol., solid content, and acidity after
amine stimulation of gastric juice did not
significantly. In the 2 duodenal ulcer-
ics, restoration of normal hemoglobin and
n Fe levels was accompanied by a 10-fold
ease in the previously reduced Fe-binding
ity. In the 8 hemorrhagic anemics Fe-binding
city was also reduced. Gel filtration re-
ed in similar elution patterns in all patients.
Fe-binding component was always found in the
-molecular-wt.-excluded fraction, and its
vity varied in the same way as that of the
e gastric juice. The results support the
ept that the Fe-binding protein gastroferrin
uction is concerned with regulation of Fe
rption in health: normal levels inhibit
rption of excessive amounts of Fe present in
diet; reduced levels permit the enhanced
rption of Fe in Fe deficiency.

SALICYLATES AND IRON ABSORPTION.
COMPETITION OF SALICYLATE AND GASTRIC
E FOR IRON. (E.) Davis, P. S. (U. Adelaide,
ralia) and D. J. Deller. Gastroenterology
):691-694, 1967.

n. of a salicylate-Fe complex in a 50:1
r ratio did not alter radioiron absorption in
al subjects. Although salicylate has the
ity to chelate Fe *in vitro*, its ineffective-
in vivo was shown to be due to the stronger
nity of gastric juice for Fe. A high mole-
r weight protein fraction in gastric juice
essfully competes with salicylates for the Fe,
ering the salicylate ineffective in Fe
rption. No evidence was found to support
proposal that a mechanism for a salicylate
ia is the formation of an inhibitory Fe-sali-
te complex.

3 A COMPARISON OF INTESTINAL ABSORPTION
IN THE RAT OF ELAIDIC, OLEIC, AND STEARIC
S FED IN THE FORM OF MIXED TRIGLYCERIDES
RISING FIVE FATTY ACIDS WITH RANDOM DISTRIBU-
. (Fr.) Lavoue, G. (Fac. Sci., Dijon,
ce) and J. Clement. Bull. Soc. Chim. Biol.
is) 49(4):379-388, 1967.

White rats (200 g) fasted for 15 hr. were given 1200 mg of food containing 20% lipids. These triglycerides were of mixed composition, containing 5 fatty acids distributed at random among the 3 positions on the glycerol: palmitic; $1\text{-}^{14}C$-stearic; $9,10\text{-}^{3}H$-oleic, (specific activity of each acid 50,000 ipm/mg); elaidic and linoleic; the percentages in moles of these acids were, resp., 26.4, 18.5, 19.7, 22.3 and 13. The thoracic lymph duct was cannulated 90 min. after feeding. Lymph was collected during a 24-hr. period and kept at 0°C. The collected lymph as well as the contents of the intestinal lumen and the mucosa scraped from the anterior two-thirds of the small intestine, were separately extracted for lipids, the triglycerides separated from the other lipids and the different triglycerides separated by silicic acid column chromatography. The 2 radioactive fatty acids were quantitatively determined by gas chromatography, and the other 3 fatty acids by differential methods. The lymphatic triglyceride determinations showed that the amount of elaidic acid incorporated was higher than the 2 labeled fatty acids; elaidic acid was preferentially located on the external positions, stearic or oleic occupying the middle position. Analysis of the luminal content and analysis of the mucosa showed that intraluminal lipolysis of triglycerides formed β-mono-elaidine which entered the mucosal cells where the freed elaidic acid was incorporated in the external positions of newly synthesized triglycerides.

7784 A LIPID-SOLUBLE INERT INDICATOR IN FAT ABSORPTION STUDIES IN THE RAT. (E.) Sie, H. G. (U. Groningen, Netherlands), A. J. Valkema and F. J. Loomeijer. J. Lab. Clin. Med. 69(6):989-996, 1967.

Wistar albino rats weighing 200-250 g were used in a long-term feeding experiment to test the suitability of lipid-soluble DC Silicone Fluid 703 (a methylphenyl polysiloxane compound) as an inert indicator in fat absorption studies. Recovery of the fluid from rat stools during the first 5 days following admin. of 536 mg by gastric tube was 96.0%, as contrasted to 93.8% when known amounts were added to rat feces *in vitro*. The fluid exerted no statistically significant influence on absorption of glyceryl-tristearate-$1\text{-}^{14}C$ in olive oil, admin. in p.o. doses of 75, 150 and 300 mg. As calculated by the inert indicator method, using Fluid 703, 88.8% of the 75 mg peroral dose was absorbed; as determined by quantitative analysis of the radioactivity in 2-day collections of stools, it was 89.2%.

7785 ABSORPTION OF CHOLESTEROL FROM A MICELLAR SOLUTION: INTESTINAL PERFUSION STUDIES IN MAN. (E.) Simmonds, W. J. (Rockefeller U., New York, N. Y.), A. F. Hofmann and E. Theodor. J. Clin. Invest. 46(5):874-890, 1967.

The absorption of cholesterol has been studied in man by perfusing the upper jejunum with a micellar soln. of bile salt, 1-monoglyceride, and cholesterol-^{14}C, with a triple lumen tube with collection sites 50-cm apart. The absorption of micellar components between the collection sites was calculated from their conc. changes relative to those of the water-soluble marker, polyethylene glycol. Bile salt was not absorbed (-3%), but micellar monoglyceride was rapidly hydrolyzed and absorbed almost completely (98%). Cholesterol radioactivity was absorbed to an intermediate extent (73%), and the absorption of chemically determined cholesterol (46%) indicated that much of the disappearance of radioactivity represented true absorption and not simple exchange. The specific activity of the perfused cholesterol fell during passage through the loop which suggests the continuous addition of nonradioactive endogenous cholesterol by the test segment. However, the decrease in specific activity may also be considered to signify exchange, in that nonradioactive molecules entered the lumen as radioactive molecules were absorbed. Plant sterols appeared in the intestinal contents during the perfusion and must have been contributed by the perfused segment. Cholesterol in the perfusate or upper collection site samples did not sediment (ultracentrifuge), but 23% of the cholesterol in the lower collection site samples was sedimentable; bile salt, as control, was not sedimentable. Solubility experiments in model systems showed that cholesterol possessed low solubility in bile salt soln.; its solubility increased markedly and in linear proportion to the amount of fatty acid or monoglyceride or both that was added to the bile salt soln. These findings suggest that polar lipid such as fatty acid or monoglyceride as well as bile salt is essential for normal micellar solubilization of cholesterol in intestinal content. They suggest the necessity of considering an insoluble sedimentable phase of particulate sterol in intestinal content as well as an oil and micellar phase for a complete description of sterol absorption. The marked difference in the rates of absorption of individual micellar components suggests that micellar lipid is not absorbed as an intact aggregate and is consistent with the view that polar lipid such as fatty acid is absorbed in molecular form by diffusion from a micellar soln. The experiments confirm previous findings demonstrating that fat absorption without bile salt absorption occurs in the upper small intestine in man.

7786 EFFECTS OF VARYING LIPID COMPONENTS OF THE DIET ON TOLERANCE, INTESTINAL ABSORPTION AND THE COMPOSITION OF SUBCUTANEOUS FAT IN THE PREMATURE INFANT. (It.) Ansanelli, V. (U. Naples, Italy), P. Tiberio and L. Lupi. Pediatria (Napoli) 74(6):989-1008, 1966.

A total of 22 premature neonates, weighing 1800-2400 g at the start of the study and born during the 32nd-38th wk. of gestation, were fed milk containing 50-100 calories per kg per day (depending on age and size), beginning on the third day postpartum and divided into 7-8 feedin One group received homogenized, pasteurized huma milk; 2 received 2 different brands of commercia powdered milk with an approx. equal content of total lipids and both mono- and polyunsaturated fatty acids (except for a considerably increased content of linoleic acid); one received acidifie partly skimmed cow's milk, also powdered, which had a significantly lower content of total lipid and a generally reduced content of unsaturated fatty acids, especially linoleic. In all 4 groups tolerance was as good as that found in children receiving mother's milk or partly skimm cow's milk. During the first 2 wk., much of the lipid content was not absorbed through the intestine, but the absorption rate increased progressively thereafter, reaching a sufficient degree to modify the fatty acid content of s.c. adipose (gluteal) tissue by the end of the first mo. At this latter time, the percentage distrib tion of mono- and polyunsaturated fatty acids in biopsy specimens derived from the gluteal region paralleled the percentage distribution of the particular milk being fed, even though this was considerably different from the distribution evidenced in biopsy specimens obtained at birth.

7787 IMPORTANCE OF BILE ACIDS AND OF AN INTACT DISTAL SMALL INTESTINE FOR FAT ABSORPTION. (E.) Austad, W. I. (Duke U. Med. Ctr., Durham, N. C.), L. Lack and M. P. Tyor. Gastroenterology 52(4):638-646, 1967.

The enterohepatic recirculation of Na taurochola 24-^{14}C was studied in 2 volunteer medical studen and 2 patients with disorders of the distal small intestine. One patient had a jejunocolic fistula created surgically for the management of obesity, and the other had irradiation for a carcinoma of the cervix. In the normal subjects the exponential decline in specific activity, cpm/mg, of Na taurocholate-^{14}C in duodenal sampl permitted estimation of the kinetics of the enterohepatic circulation. These observations, when compared with previous investigations, suggest that approx. 30% of the cholate pool in normal man consists of cholic acid conjugated wi taurine. Significant steatorrhea was demonstrab in both patients. However, their proximal small intestine appeared normal from morphological and biochemical studies. The Schilling test was abnormal in both patients. A virtual absence of enterohepatic recirculation for Na taurocholate-^{14}C was demonstrated in 2 patients. In addition recirculation of unconjugated or newly conjugate cholate-^{14}C was negligible. These experiments demonstrate clearly the importance of the distal small intestine in maintaining the enterohepatic recirculation of Na taurocholate. They also poi up the importance of an intact enterohepatic circulation of bile salts to the overall process of lipid absorption in man.

7788 CONCENTRATION AND COMPOSITION OF FATTY ACIDS OF THORACIC DUCT LYMPH LIPIDS FROM RABBITS. (E.) Kotani, M. (U. Kyoto Med.

., Japan), K. Seiki, A. Yamashita, A. Takashima,
Nakagawa and I. Horii. Amer. J. Physiol.
(1):235-238, 1967.

-liquid chromatography was used to study
conc. and composition of fatty acids of
racic duct lymph lipids from rabbits in high
low absorptive states of lipids. The conc.
the triglyceride fatty acids greatly increased
lymph during intensive absorption. The phos-
olipid fatty acids and free fatty acids also
creased markedly, but to a lesser degree than
the triglyceride fatty acids. There was
ther an increase nor a change in the cholesterol
ter fatty acids. The fatty acid composition of
iglycerides and free fatty acids varied con-
derably in high and low absorptive states of
pids. Composition of triglycerides in lymph
ring intensive absorption was similar to that
the dietary triglycerides. In contrast, there
re few changes in the fatty acid composition of
olesterol esters and phospholipids.

89 EFFECTS OF PORTAL SYSTEMIC SHUNTING ON INTESTINAL ABSORPTION IN THE DOG
D IN MAN. (E.) Price, J. B., Jr. (Columbia
, New York, N. Y.), W. McCullough, L. Peterson,
C. Britton and A. B. Voorhees, Jr. Surg.
nec. Obstet. 125(2):305-310, 1967.

rge (2-3-cm) and small (0.5-1.0-cm) portacaval
unts were created in dogs, and intestinal
sorption rates of xylose, urea and ammonia
re measured before and after the shunts.
atistically significant increases of 50% in
lose absorption and of 16% in ammonia absorption
re found in animals with large shunts, while a
aller increase of 6.5% in urea absorption was
ted. There were no significant changes in
lose, ammonia or urea absorption in dogs with
all shunts. The absorption of D-xylose was
asured in 13 patients (nonascitic) with portal
pertension before and after a portal systemic
unt; 10 of the patients had cirrhosis of the
iver and 3 had portal vein thrombosis; there was
highly significant av. increase of 31% for the
tire group after the shunt. The absorption of
-xylose was also determined in 10 patients (who
erved as controls) before and after cholecys-
ectomy; there was no change in xylose absorption.
t is suggested that these changes in intestinal
bsorption were due to an augmented microcircula-
ion in the intestine after a hemodynamically
ffective portal systemic shunt. This increased
ntestinal absorption of ammonia and other
assively absorbed substances is thought to
e another factor tending to produce neurologic
omplications after a large portal systemic shunt.

790 INTESTINAL TRANSPORT OF VALINE AS AFFECTED BY IONIC ENVIRONMENT. (E.)
eiser, S. (Indiana U. Sch. Med., Indianapolis)
nd P. A. Christiansen. Amer. J. Physiol.
12(6):1297-1302, 1967.

Everted intestinal sacs derived from fasting, male Wistar rats were incubated for 60 min. at 37°C with Krebs-Ringer bicarbonate buffer, pH 7.4, containing 118 millimoles NaCl, 25 millimoles $NaHCO_3$, 4.7 millimoles KCl, 2.5 millimoles $CaCl_2$, 1.2 millimoles $MgSO_4$, 1.2 millimoles monobasic potassium phosphate and both radioactive and nonradioactive L-valine to a final conc. of 3 millimoles (1-10 x 10^3 cpm/ml). Isotonic replacement of half the indicated amount of NaCl by LiCl, KCl, mannitol or sucrose resulted in 66.4%, 39.0%, 15.3% and 13.7% inhibition of net valine transport, resp. Substitution of choline chloride, as above, exerted no appreciable effect in the presence of Na ion conc. as low as 30 mmoles; however, below that conc. level, valine transport decreased abruptly to the point of virtually total inhibition in the absence of Na. Optimal valine transport, which occurred over a pH range of 5-8, did not appear to require the presence of Mg, Ca, K or phosphate ions in the incubation medium, but isotonic replacement of Na and KCl by the corresponding sulfates inhibited transport by 25-30%. Following 1 hr. incubation of the sacs in medium containing 118 millimoles Na, intracellular Na content increased to approx. 4 times initial levels.

7796 GASTROINTESTINAL ABSORPTION OF ^{59}Fe AND TISSUE DISTRIBUTION OF ABSORBED RADIOIRON IN PROTEIN-DEFICIENT RATS AND RESTORED WITH A DIET CONTAINING CASEIN OF DIFFERENT MIXTURES OF AMINO ACIDS. COMPARATIVE EFFECTS OF THESE DIETS ON ERYTHROPOIESIS. (Fr.) Aschkenasy, A. Arch. Sci. Physiol. (Paris) 21(2):127-151, 1967.

7797 THE PARTICIPATION OF THE NERVOUS SYSTEM IN THE HISTAMINE SECRETION OF THE GASTRIC GLANDS. (Rus.) Maevskaia, N. V. (Donets Med. Inst., USSR). Biull. Eksp. Biol. Med. 62(11): 13-17, 1966.

The role of the nervous system in the reaction of gastric glands to histamine was studied in 5 dogs with a Pavlov pouch and in 6 dogs with a Heidenhain pouch by the method of pharmacological and anatomical denervation. The admin. of hexamethonium (6-10 mg/kg, s.c., or 2 mg/kg, i.v.) 5-30 min. before histamine resulted in a decrease in secretion by an av. of 43.9% in 10 of 11 dogs. Under the action of hexamethonium, the latent period of histamine secretion is prolonged (i.e., from 10.7 to 13.0 min.), acidity of the gastric juice was decreased (i.e., from 119.0 to 99.1 ml), as was the amount of HCl secreted (i.e., from 41.5 to 19.1 mg). Bretylium compounds (9-10 mg/kg, s.c.) admin. 30 min. before histamine increased secretion in 3 dogs with Heidenhain's pouch; acidity of gastric juice was increased, as well as the total secretion of HCl (from 33.2 to 68.2 mg) and the amount of proteolytic enzyme (from 99.25 to 600 special U). In 3 of 4 dogs, denervation caused a decrease in secretion of gastric juice (i.e., from 8.39 to 3.05 ml). In the dog in which hexamethonium was ineffective, denervation also did not affect secretion. The action of bretylium compounds on the secretion was accomplished by blocking neural impulses. Therefore, gastric gland reactivity to histamine is defined by a correlation of parasympathetic and sympathetic actions on the secretory apparatus.

7798 THE ROLE OF THE HYPOPHYSIS IN CONTROL OF SECRETION AND TROPHIC FUNCTION OF GASTRIC MUCOSA. (Rus.) Lipovsky, S. M. (Sanit. Hyg. Med. Inst., Leningrad, USSR) and A. S. Zaichik. Pat. Fiziol. Eksp. Ter. 11(1):63-68, 1967.

In a total of 80 rats, gastric secretion was studied on adult male rats (wt. 200-220 g) with plexiglass fistulae, which underwent hypophysectomy 4-6 wk. later; rats without fistulae were used to study daily diuresis and excretion of pepsinogen after hypophysectomy. The time of placement of the fistula into the stomach (from the eleventh to the seventy-first day) had no evident effect on the amount of the excreted juice and its composition. By 7-19 days after hypophysectomy, total acidity was decreased an av. of 40% and the amount of free HCl by 39% compared to initial values; the amount of excreted gastric juice, pepsin conc. and pepsin excretion remained unchanged. Initially diuresis was increased after hypophysectomy, and later it became normalized. Thus, hypophysectomy had no essential effect on the amount of excreted gastric juice; the pepsin-forming function of the chief cells was significantly reduced, and pepsinogen excretion in the urine was not disturbed. Rats which had been fasted for 48 hr. were laparotomized and a ligature was imposed on the pylorus; after narcosis had ended, the rats were given 2 ml of a 7% decoction of dry cabbage containing 3% NaCl and 24 hr. later they were sacrificed, thei stomachs removed and the mucous membrane examine Hypophysectomy did not impede development of ulcerative lesions in the gastric mucous membran In the rats with hypophysectomy the number of ulcers was greater (98) than in rats without hypophysectomy (64). At 13-18 days after operation, the gastric mucous membrane in hypophysect mized rats was increasingly ulcerogenic.

7799 HISTIDINE DECARBOXYLASE IN THE STOMACH OF THE RAT. (E.) Radwan, A. G. (U. London) and G. B. West. J. Pharm. Pharmacol. 19(5):305-312, 1967.

A supernatant extract of homogenized rat stomach was prepared. Stomachs of other rats were cut into fundic and pyloric sections. Stomach enzyme was measured and compared in fed-rats and rats starved for 24 hr. Whole-stomach enzyme showed 2 pH peaks, 5.6 and 7.6. Only the pH 5.6 peak was present in fundic sections, only the 7.6 in pyloric. Max. enzyme activity in fundic section was 10 times that in the pylor At pH 7.6 there was a linear relationship betwee substrate conc. and pyloric enzyme activity; the plot was hyperbolic at 5.6 for fundic enzyme. The apparent Michaelis constant (K_m) of the enzyme was 1.07×10^{-4} g/ml (7×10^{-4} M) for fundic and 2.67×10^{-4} g/ml (1.7×10^{-3} M) for pyloric. Rates of reaction of both preparations, at the resp. pH optima, increased with increasing enzyme conc. At optimum pH both preparations showed a linear relationship between enzyme activity and length of incubation. Activity of pyloric enzyme disappeared rapidly at -15°, with only 10% of the activity left after 14 days. Cold had little effect on fundic enzyme. Activit of pyloric enzyme was increased by 20% by 20 mg benzene, while fundic enzyme was unaffected. Both α-methylhistidine and L-α-methyldihydroxyphenylalanine inhibited activity of pyloric enzyme but had no effect on fundic, even at a conc. of 1 mg. Dihydroxyphenylalanine and serotonin had no effect on fundic enzyme, but competed with substrate for pyloric enzyme. Starvation caused a 97% inhibition of fundic enzyme activity, but only 21% of pyloric; a 33% reduction in histamine content of pyloric portion, but no effect on fundic. It is suggested that fundic histamine is kept at a low basal level and that histamine formed by high enzymatic activity in this portion is catabolized at a fast rate or transported to other parts of the body. Two such enzymes are also found in the mouse stomach; pH optimum of fundic enzyme is 5.6 of pyloric 7.6-8.0.

7800 PENTAGASTRIN AS A STIMULANT OF MAXIMAL GASTRIC ACID RESPONSE IN MAN:

LTICENTRE PILOT STUDY. (E.) Fitzgerald, J. D.
.I. Pharmaceuticals, Alderly Park, Cheshire,
and). Lancet 1(7485):291-295, 1967.

combined experiences of more than 150 tests
different medical centers were examined in
r to determine if acid responses as large as
e to max. doses of histamine could be obtained
pentagastrin. The incidence and severity
ide effects were also compared with histamine.
experience was with surgical patients suffer-
from duodenal ulcers, although observations
uded a few patients without gastrointestinal
ase, and health volunteers. Timing pattern
ies of s.c. and i.v. admin. were made to
are max. responses to both drugs. It was
luded that gastric acid responses as great
hose to max. doses of histamine can be
ined with pentagastrin from the intact stomach.
ppeared that suitable doses for max. response
entagastrin are approx. 6 μg/kg s.c., and
/kg/hr. by continuous i.v. admin.

FUNCTION OF ACINAR CELLS AND CELLS OF
THE PAROTID GLAND DUCTS UNDER LONG-
ING STIMULATION. (Rus.) Nechaeva, N. V.
ertzov Inst. Animal Morphol., Acad. Sci.
ow) and V. I. Dmitrieva. Arkh. Anat. 52(3):
8, 1967.

ale albino rats (110-140 g), after feeding
p.o. admin. of distilled water (controls),
absolute rate of protein increase in the
plasm of acinar cells or salivary tubule
s of the parotid gland was 2.32 or 1.16/mm^2,
. A decrease of cellular dry wt. of acinar
s during the initial 10 min. was followed by
adual increase of protein in the cytoplasm.
ubular cytoplasm, max. accumulation occurred
r 60 min. In rats that had been fed and
n. p.o. with 0.5% HCl, the dry cytoplasmic
of the acinar cells decreased, but the
tion of secretion was approx. 40 min.; the
city of increase of protein in the cytoplasm
cinar or salivary tubule cells was 1.47 or
pg/min., resp. The largest increase of
lar cell dry wt. was found 60 min. after food
chemical stimulation. Rats which were fed
admin. 1.5% HCl exhibited excretion, but its
tion increased when compared to the above
ations of the experiment. An accumulation
ytoplasmic protein occurred again in the
od between 120 and 180 min. The velocity of
ein increase in acinar cells and in salivary
le cells was 0.78 and 2.47 pg/min., resp.
ccumulation of proteins in the tubular cells
rred after 40 min. Therefore, the amount of
ar cell protein decreased after repeated
of HCl when compared to controls, but total
wt. of the acinar cells was higher than that
controls. Apparently, additional stimulation
the salivary cells by HCl decreased synthesis
secretory proteins, i.e., it caused the
retion of saliva which was poor in organic
pounds, without disturbance of structural
tein synthesis. Alteration in the speed of
protein accumulation in tubule cells during the process of prolonged stimulation of the parotid gland and the marked increase of protein in tubular cells during the decrease of protein synthesis in the acinar cells is a sign of protein synthesis and not of simple protein adsorption by salivary tubule cells.

7802 THE EFFECT OF YEAST ON GASTRIC SECRETION IN DOGS. (Rus.) Zitler, T. N. (Sci. Res. Inst. Nutr., Acad. Med. Sci., Moscow) and S. Y. Mikhlin. Vop. Pitan. 26(1):53-58, 1967.

Dry brewer's yeast (50 g), given to 1 dog with a Pavlov pouch and to 1 with a Heidenhain pouch, was a very strong stimulant of gastric secretion. Yeast-induced secretion was markedly superior to that induced by bread, meat, beef bouillon, etc. In the Pavlov dog, yeast-induced gastric secretion was higher (31.75 ml after 3 hr.) than secretion induced by yeast and bread (13.1-16.8 ml, and 10.0-13.6 ml, resp., after 6 hr.). Yeast-induced secretion was higher in acidity and lower in pH and pepsin content than meat- or bread-induced secretion. Yeast- and beef buillon-induced secretion was more acidic and lower in pH than that induced with meat and bread. There was a latent period of 10 min. in the Pavlov dog. In the Heidenhain dog, bread induced a secretion of 2.0-4.5 ml and of low acidity after 6 hr.; the latent period fluctuated from 45-60 min. After feeding with meat, gastric juice secretion reached 4.1-7.8 ml. Yeast-induced secretion amounted to 35.8 ml. Max. secretion of gastric juice in the Pavlov dog occurred after 1 hr., and in the Heidenhain dog after 2 hr. Both secretions were qualitatively identical. Yeast-induced gastric secretion markedly exceeded that induced by beef bouillon and cabbage juice. The stimulatory effect of yeast may be related to its higher content of vitamins, mostly of the B complex when compared to the other stimulants. The fact that yeast greatly increases gastric secretion may be of clinical importance.

7803 THE STUDY OF THE PH OF THE FASTING GASTRIC CONTENTS IN HEALTHY PERSONS BY MEANS OF THE PH RADIOCAPSULE. (Rus.) Belousov, A. S. (Cent. Inst. Advanced Train. Phys., Moscow) and B. E. Vochal. Vrach. Delo (1):42-47, 1967.

In contrast to the results of thin sound detection, which showed the presence of free HCl (on an empty stomach) in 50% of 67 persons studied (42 men, 25 women; 18-47 yr. old), use of radiotelemetric registration showed that 50 of 67 had free HCl (pH 1-5). Three basic types of gastric secretion were demonstrated in fasting, healthy subjects by means of prolonged radiotelemetric pH studies of the stomach contents; these were excitable, inhibitory and inert. The irritable or excitable type of secretion, which was found in 50 individuals, was characterized by a larger or smaller amount of gastric content of pronounced acidity (total acidity sometimes reached 130; free HCl, 100-120 titration U) and digestive strength; entrance of the radiocapsule into the stomach was followed by stabilization of the pH (approx. 2-0.8), which remained at this level during the entire period of observation. The inhibitory type of secretion, found in 8 individuals, was characterized by the prevalence of gastric mucus in the gastric contents and the absence of free HCl; total acidity did not exceed 20 titration U, the digestive strength was zero and pH was 7-8 during all of the observation period. The inert type of secretion was found in 9 individuals and was characterized by the absence of free HCl during the first 20-30 min. of observation; the amount of gastric contents fluctuated, consisting chiefly of mucus, and pH was 7.8-9.0. In addition, by the titration method (markedly later) and by the radiocapsule pH method (markedly earlier), free HCl, reaching max. values toward the end of the second hr. of study, was found in the gastric contents; pH was 1-3. Admin. of drinking soda (0.5 g) in water (30 ml) to individuals with the excitable type of secretion produced a rapid (15-30 sec.) increase of pH to 7-9, which lasted approx. 5-10 min.; this was followed by a rapid (1-2 min.) return to initial values. In those with an inert type of secretion, the admin. of drinking soda in water caused a marked increase of pH from 1-2 to 8-9, which lasted 10-20 min. and this was followed by a gradual decrease to initial values. Thus in healthy persons, the velocity and intensity of alkali neutralization and the time required for restoration of the initial pH values, was dependent on the type of gastric secretion.

7804 INFLUENCE OF ACETYLCHOLINE AND BENACTYZINE ON CENTRAL CHOLINERGIC STRUCTURES REGULATING GASTRIC SECRETION.

(E.) Anichkov, S. V (Inst. Exp. Med., Leningrad, USSR) and L. L. Grechishkin. Arch. Int. Pharmacodyn. 166(2): 417-423, 1967.

In dogs the common carotid was exteriorized into a cutaneous flap, the external carotid ligated and the carotid sinus denervated. After recovery a catheter was easily placed by puncture into the carotid artery and could be left in place several wk. The dogs were also prepared with gastric fistulae. Acetylcholine (5 μg/kg/min. i.v.) increased gastric secretion; a similar effect was produced by carotid infusion of 0.25 μg/kg/min. Histamine (0.001-0.25 μg/kg/min.) was equally effective by the i.v. or carotid route. Benactyzine (0.25 μg/kg/min. by intracarotid route blocked secretion induced by intracarotid acetylcholine while the same dose of benactyzine i.v. was without effect, and was less than the dose necessary to produce peripheral inhibiting effects. Gastric secretion induced by sham feeding in esophagectomized dogs was blocked by intracarotid infusion of 0.5 μg/kg/min. of benactyzine. the same dose i.v. was about a third as effective. The depression in secretion following intracarotid infusion is attributed to centrally-located cholinergic structures involved in the regulation of gastric secretion.

7805 VASODILATATION, A METHOD FOR IMPROVING ACID-PEPTIC ACTIVITY OF THE STOMACH.

(E.) Fikry, M. E. (Alexandria U., Egypt). Acta Gastroent. Belq. 30(1):82-90, 1967.

The effects of 2 vasodilator agents, nylidrin HCl and B-pyridylcarbinol were studied on gastric secretion in 57 patients ranging in age from 20-40 yr. None of the patients were suffering from any disease of the gastrointestinal tract. Basal gastric secretions were first collected and then 30 min. of the secretions following 2.5 mg of histamine. Nylidrin was admin. to 30 patients, 6 mg/6 hr. for 4 days with 5 mg i.m. the evening and morning preceding tests. B-Pyridylcarbinol was admin. to 27 patients 50 mg 8 hr. for 4 days with 100 mg i.m. the evening before and the morning of the test. Secretions were collected in the same manner before and after the period of drug admin. About 65% of the patients reported flushing heat headache, etc. when on the drugs. Of 30 patients receivin nylidrin, 21 were hyposecretors; 13 of these had improved acid levels following the drug, some to normal levels. Of 7 normal secretors, 3 showed higher acid levels. An improved response to histamine was shown by 14 of 19. Patients receiving B-pyridylcarbinol showed a similar response: 64% increased acid levels in basal state, 77% showed an improved response to histamine. With both drugs, patients that were resistant to histamine showed some response after therapy. Vasodilators are suggested as possibly of value in the treatment of hyposecretors due either to disease, old age, or constitutional reasons.

7806 THE EFFECT OF CORTISONE ON GASTRIC HISTAMINE CONTENT AND GASTRIC SECRETION IN PYLORUS LIGATED GUINEA-PIGS.

(E.) Heisler, S. (McGill U., Montreal, Canada) and E. M. Kovacs. Brit. J. Pharmacol. 29(3):329-334, 1967.

Male guinea pigs were fasted for 28 hr., the pylorus ligated under ether anesthesia and deprived of food and water until sacrificed (overdose of ether) 18 hr. later. Before respiration stopped, stomachs were ligated at the esophageal end, removed, and blotted dry on filter paper. The greater curvature was incised and the contents emptied into calibrated centrifuge tubes. The stomach was further opened along the greater curvature, examined for lesions, and extracted for histamine after 2-3 hr. Sixteen animals were inj. s.c. with 100 mg/kg cortisone daily for 10 days. The animals were killed 24 hr. after the final dose and histamine content of the whole stomach, or antrum and corpus, was determined. Av. histamine level in 11 cortisone-pretreated animals (6.64 μg/g) was significantly lower than that in 15 controls (10.20 μg/g). Av. contents of the

rum and corpus, which were the same in untreated
mals (9.92; 9.78 were equally and significantly
ered by cortisone pretreatment (6.64; 6.61).
ht received a single s.c. inj. of 100 mg/kg
ediately after ligation; 6 received this dose
ly for 3 days; 12 for 10 days. Compared with
trol pylorus-ligated animals, a single dose
ered av. gastric histamine content by 16.8%;
nj. by 29.9%; 10 inj. by 27.6%. Compared with
se controls (pH 4.08; free HCl 0.14 mEq; total
d 0.49 mEq), a single inj. produced a fall in
and a slight rise in free and total acidity
gastric juice (2.98; 0.38; 0.82). These
ects were augmented by 3 inj. (1.86; 0.65;
7) and further so by 10 inj. (1.78; 0.80;
1).

07 GASTRIC SECRETORY RESPONSES TO DRUGS AFFECTING ADRENERGIC MECHANISMS IN RATS.

) Bass, P. (Parke, Davis & Co., Ann Arbor,
ch.) and M. A. Patterson. J. Pharmacol. Exp.
er. 156(1):142-149, 1967.

series of vasoactive or adrenergic drugs was
aluated for effects on gastric secretion in
lorus-ligated rats. Dose levels (mg/kg body
.) were calculated on the basis of content of
tive moiety; admin. was by s.c., i.v., or
traduodenal inj. Those with s.c. or intra-
odenal inj. at time of ligation were sacrificed
hr. later. Results of replicated experiments
re pooled and data tabulated for each drug,
sp. Vol. of secretion/100 g body wt. was
lculated. The value for 50% reduction of
cretion (ED$_{50}$) was calculated graphically from
plot of percentage secretion against mg/kg
se, and relative potencies of drugs inj. were
ferred from ED$_{50}$ values. Drugs with a s.c. ED$_{50}$
ss than 10 mg/kg in rats were considered potent
tisecretory agents. Peripheral vasoconstrictors
vasodilators had no consistent effect on
cretion. Vasoconstrictors such as norepinephrine
D$_{50}$ 0.25), epinephrine (0.28) and vasopressin
.26) were antisecretory, while angiotensin and
-dihydroxy phenylalanine had no effect. Of the
sodilators, isoproterenol (0.36) was antisecre-
ory, while bradykinin had no effect. Most
drenergic blocking agents were weakly antisecre-
ory. Drugs preventing catecholamine uptake were
ntisecretory and were more potent than those
reventing catecholamine release. Little effect
secretion was exhibited by sympathomimetic
mines with indirect or mixed actions or by
nhibitors of catecholamine metabolism. No effect
gastric secretion was exhibited by compounds
hat interfere with catecholamine synthesis by
nhibition of dopamine-β-hydroxylase or decarboxy-
ase enzymes. Catecholamines exerted a gastric
ntisecretory effect in the rat independent of
asoactive properties. It is concluded that
rugs which increase the biological half-life
f catecholamines decrease gastric secretion.

808 BALANCE OF THE GONADOTROPIC AND GASTRIC ANTISECRETORY ACTIVITIES IN THE PURIFICATION OF UROGASTRONE.

(E.) Lugaro, G. (U. Milan, Italy), M. M. Casellato and E. Crespi. Folia Endocr. (Roma) 19(3):378-390, 1966.

Gastric antisecretory activity measured by inhibition of gastric secretion following pyloric ligation in rats and gonadotropic activity evaluated on impuberal male and female rats by the method of Lugaro *et al.* were determined for various fractions of urogastrone. After gel filtration on Sephadex G-25 the gastric antisecretory activity was restricted to a single fraction, which, however, still possessed gonadotropic activity. Treatment of this extract with 1 M formic acid preceding gel filtration on G-100 yielded a fraction designated Ug G-100 possessing 31,000 antisecretory U/g (one U/100 g body wt. i.v. inhibited gastric secretion 50%) with an excellent yield. The substance appeared to be homogeneous to electrophoretic and ultracentrifugal methods in 1 M formic acid, but not in alkaline soln. (2 components, S = 5.59 and 1.89). The gonadotropic activity was retained by Ug G-100. The hypothesis that gonadotropic activity is linked to the integrity of the urogastrone molecule is rejected.

7809 GASTRIN-LIKE PENTAPEPTIDE I.C.I. 50 123: A POTENT GASTRIC STIMULANT IN MAN.

(E.) Konturek, S. J. (First Int. Dis. Clin., Cracow, Poland). Amer. J. Dig. Dis. 12(3):285-292, 1967.

Studies were carried out on 12 normal controls, 8 patients with duodenal ulcer, and 5 duodenal ulcer patients undergoing vagotomy and pyloroplasty. Continuous suction was used to collect gastric secretions by Levin tube. Collections were made before and after admin. of ICI 50, 123, 6 μg/kg s.c. or 0.024-6 μg/kg/hr. i.v. Histamine 40 μg/kg s.c. or 10-40 μg/kg/hr. was admin. for comparative purposes. The gastrin-like pentapeptide ICI 50, 123 was a more effective stimulant of gastric secretion in man than histamine and produced a max. acid output at 1.2 μg/kg/hr. i.v. or 6 μg/kg s.c. Atropine (1 mg s.c.) reduced pentapeptide- or histamine-induced acid secretion by 48 and 27%. After vagotomy a standard dose of pentapeptide produced an acid output 45% less than preoperatively. Histamine response was reduced by 30%. These data suggest that cholinergic innervation plays an important role in the effect of pentapeptide on gastric secretion. It is concluded that the gastric secretory test with pentapeptide has an advantage over other secretory methods insofar as it provides a reproducible, safe, and physiological stimulation of the stomach.

7810 COMPARATIVE EFFECTS OF GASTRIN II AND HISTAMINE ON PEPSIN SECRETION IN MAN.

(E.) Makhlouf, G. M. (Western Gen. Hosp., Edinburgh), J. P. A. McManus and W. I. Card. Gastroenterology 52(5):787-791, 1967.

Seven subjects (3 duodenal ulcer, 2 gastric ulcer, 2 normal) were each tested on separate occasions with histamine (40 μg/kg) or gastrin II (1 μg/kg), admin. s.c. Two 20-min. basal samples (spontaneous secretion) were collected prior to each test. Stimulated secretion was collected every 5 min. for 80 min.; eight 10-min. samples were collected for analysis. Following both gastrin and histamine, peak vol. and acid outputs occurred simultaneously at 30-50 min. Av. vol. and acid output during the hr. following stimulation were similar for both. After both, pepsin rose to an early peak at 15-20 min., but declined more rapidly with histamine. In each subject, both peak output and 1-hr.-output were significantly higher after histamine than gastrin; av. rise was 4-fold with histamine, 3-fold with gastrin. Output pattern of nitrogen followed that of pepsin; in all but 1, output after histamine (3-fold) was higher than that after gastrin (2-fold). After a short-lived initial rise, conc. of pepsin fell rapidly with gastrin, more slowly with histamine, to a level equal to half the basal conc. Nitrogen varied inversely with acid which rose quickly to a plateau. Basal acid output correlated with stimulated acid output and with basal pepsin output, and the latter correlated with stimulated pepsin output. Pepsin output, although 30% lower after gastrin, was highly correlated with corresponding pepsin output after histamine. Pepsin outputs on stimulation also correlated with corresponding acid output. Amount of pepsin secreted with each mEq of acid was higher under basal conditions (3.3 kU) than after histamine (1.1 kU) or gastrin (0.8 kU). Nitrogen outputs after gastrin correlated with corresponding output after histamine. Amount of nitrogen accompanying secretion of 1 mEq of acid was higher under basal conditions (13.3 mg) than after histamine (3.1 mg) or gastrin (2.3 mg).

7811 THE RELATIVE EFFECT OF AN ANTICHOLINERGIC DRUG, GLYCOPYRROLATE, ON BASAL GASTRIC SECRETION AND SWEAT- AND SALIVARY-GLAND ACTIVITY. (E.) Juniper, K., Jr. (U. Arkansas Med. Ctr., Little Rock). *Amer. J. Dig. Dis.* 12(5):439-448, 1967.

The fingertip sweat gland count and the salivary flow technics were used. For gastric analysis, a Levin tube was placed in the stomach under fluoroscopic monitoring after an 8-10 hr. fast; the fasting contents of the stomach were removed by hand aspiration, and the tube was connected to a suction pump with intermittent automatic release of vacuum; after a 30-min. equilibration period, fractions were collected at 20-min. intervals, and vol., pH, and acid content were measured. Subjects were 5 experimental volunteers with hyperchlorhydria by betazole testing; they were not then receiving drugs known to affect gastric secretion; a minimum of 2 days elapsed between tests in a given patient. Dose levels tested were selected as the study progressed; after an initial s.c. dose of 0.20, followed by 0.10 mg of glycopyrrolate, both high and low doses were tested. After a control period of 2 hr., the test dose was given i.m. and observatio were continued until the period of peak drug effect had passed. Subjects were followed for 3-5 hr. after drug admin. Placebo was 0.9% NaCl; test doses of glycopyrrolate were 0.02, 0.05, 0.10, 0.20, 0.30 mg. Both tests (fingerti sweat gland, salivary flow) were reliable indicators of glycopyrrolate effect, but the sweat gland test was more reproducible and sensitive than the salivary flow technic. Glyco pyrrolate had a significantly greater suppressiv effect on basal gastric secretion than on sweati or salivary flow. The subjective symptom of dry mouth correlated well with sweat gland activity and salivary flow. Both tests are concluded to be useful objective measures of side effects in the evaluation of anticholinergics in gastric secretion.

7812 ENERGY SOURCES FOR GASTRIC SECRETION: SUBSTRATES. (E.) Alonso, D. (San Francisco Gen. Hosp., Calif.), K. Nigon, I. Dorr and J. B. Harris. *Amer. J. Physiol.* 212(5):992-1000, 1967.

A thorough study of the utilization of exogenous and endogenous substrates seemed to be a prerequisite to studying the effects of adenosine-3',5'-phosphate on the metabolism of amphibian gastric mucosa *in vitro*. Water-soluble salts of short- and medium-chain fatty acids and ketones stimulated acid secretion and respiration. Lesser stimulation was produced by long-chain fatty acids complexed to albumin. Amino acids and intermediates of glycolysis did not affect acid secretion or respiration except for a small enhancement by pyruvate. However, exogenous glucose and pyruvate inhibited glycogen breakdow and increased lactic acid formation. The principal limitation to carbohydrate utilization appears to lie somewhere in the steps whereby pyruvate is converted to either acetyl-coenzyme A or oxalacetate. Histamine enhanced glycogenol sis in mucosa incubated in chloride soln. but not in glucuronate soln., showing that utilization of endogenous glucose contributed directly to the secretory process. The lipid content of serum and mucosa constituted a significant source of energy. Mucosal triglyceride and glycogen content decreased with incubation. The respiratory quotient varied between 0.7 and 1.0 in different mucosae.

7813 EVALUATION OF THE CEPHALIC PHASE OF GASTRIC SECRETION: COMPARISON BETWEEN SHAM FEEDING MEAT AND TEASING WITH MEAT ON CANINE GASTRIC SECRETION. (E.) Schapiro, H. (U. Tennessee Med. Units, Memphis), L. D. Wruble, L. G. Britt and S. R. Evans. *Amer. Surg.* 33(5):398-400, 1967.

Six dogs were prepared with esophagosotomies and gastric cannulae; 2-3 wk. after surgery, these 24-hr.-fasted dogs were restrained in

fied Pavlov frames; gastric secretion was
ected and vol. and acidity were measured;
dog served as its own control. In 1 series
20 experiments (Group 1), the dogs were sham-
a meat meal for 15 min., and gastric juice
collected every 15 min. for 2 hr. In Group
20) the dogs were teased with meat for 15 min.,
gastric juice was again collected every 15 min.
2 hr. Three other dogs were prepared with
tric cannulae; in 8 studies they were fasted
48 hr. and then teased with meat; gastric
ce was collected every 15 min. for 1.5 hr.
Group 2, after a latent period of 5-10 min.,
re was a sharp increase in gastric secretion
t lasted 30-45 min.; in 11, gastric secretion
rply increased in each dog and remained
vated for over 2 hr. The av. total acid output
hr. in Group 2 was 56-75% of that in Group 1.
sing dogs with meat after a 48-hr. fast did
evoke a longer or greater response than that
n dogs fasted only 24 hr. The minimum value
each trial in Group 1 was greater than the
. value obtained in any trial in Group 2.

4 EFFECT OF TRUNCAL VAGOTOMY ON ACID AND
PEPSIN RESPONSES TO HISTAMINE AND
TRIN IN DOGS. (E.) Emås, S. (VA Res. Ctr.,
Angeles, Calif.) and M. I. Grossman. Amer.
Physiol. 212(5):1007-1012, 1967.

d and pepsin secretion in response to graded
es of histamine and hog gastrin extract was
died before and after truncal vagotomy in dogs
h gastric fistulas. Before vagotomy histamine
gastrin produced the same max. rate of acid
retion. Truncal vagotomy shifted the dose-
ponse curves for both histamine and gastrin
the right; max. responses were unaltered but
ger doses were required. Before vagotomy max.
sin response to histamine occurred with a
dose that produced submaximal acid response;
her doses depressed pepsin secretion. Max.
sin response to gastrin occurred with a dose
t produced nearly max. acid response. Truncal
otomy shifted the dose-response curves for
sin to the right, reduced max. pepsin response
histamine but did not alter that to gastrin.
ncal vagotomy reduced the responsiveness of
gastric glands to both histamine and gastrin
regard to both acid and pepsin secretion.

5 SODIUM PENTOBARBITAL DEPRESSION OF
HISTAMINE- OR INSULIN-STIMULATED
TRIC SECRETION. (E.) Powell, D. W. (U.
bama Med. Ctr., Birmingham) and B. I.
schowitz. Amer. J. Physiol. 212(5):1001-1006,
7.

retion of H, Cl, Na, K, and pepsin, stimulated
infusion of histamine (1 mg base/hr.) and
ulin (10 U) was studied in 5 dogs with gastric
nulas during sodium pentobarbital anesthesia
mg/kg) and also in the unanesthetized state.
tamine-stimulated water secretion was inhibited
by sodium pentobarbital which produced
suppression of vol. but not of H or Cl conc. and left the hyperosmolality of gastric juice relative to plasma (1.03) unchanged. These findings were interpreted as representing a reduction in the number of actively responding parietal cells, but not in the responsiveness of each cell, possibly by a reduction in effective mucosal blood flow. Despite an equivalent degree of hypoglycemia, the gastric juice vol. response to insulin was much more strongly (77%) inhibited, and not only vol. but also the conc. of H was depressed. Pepsin secretion was inhibited similarly by sodium pentobarbital regardless of the stimulus. These findings suggest a more direct and probably vagolytic effect of sodium pentobarbital on the hypoglycemic stimulus, to which must be added the direct electrolyte inhibiting effect of insulin and the nonspecific sodium pentobarbital effect typified by the histamine results.

7816 ALTERED THYROID FUNCTION IN THE RAT. EFFECTS ON GASTRIC SECRETION AND VITAMIN B_{12} METABOLISM. (E.) Biggs, J. C. (Radcliffe Infirm., Oxford, England) and L. J. Witts. Gastroenterology 52(3):494-504, 1967.

Hyperthyroidism was produced in rats by means of sodium-l-thyroxine (1 ml/liter in drinking water) and hypothyroidism by means of carbimazole (0.05% in drinking water). Studies of gastric secretion in response to max. histamine stimulation (histamine acid phosphate 50 mg/kg s.c.) performed at up to 230 days revealed no significant change in gastric acidity of the hyperthyroid rats, whereas in the hypothyroid rats there was a temporary increase in gastric acidity followed by a return to normal. In the absence of histamine stimulation, a significant fall in the conc. and output of acid was noted in the hyperthyroid rats. A slight polycythemia was observed in the hyperthyroid rats and a normochromic normocytic anemia in the hypothyroid rats. Vitamin B_{12} absorption was normal in the hyperthyroid animals and reduced significantly in the hypothyroid group. This was found to be due to a disturbance in intestinal absorption, as the intrinsic factor activity of these rats was normal. Long-term hyper- and hypothyroidism had no effect on the histology of the gastric mucosa.

7817 EFFECT OF LOCAL GASTRIC TRAUMA ON GASTRIC RESPONSE TO HISTAMINE STIMULATION. (E.) Milton, G. W. (U. Sydney, Australia), F. O. Stephens, R. Maletz and G. A. Maxwell. Amer. J. Dig. Dis. 12(5):456-464, 1967.

The effect of injury on the gastric mucosal response to histamine stimulation has been investigated in dogs by 2 technics. On exposing the intact surface of the stomach to several kinds of trauma, e.g., friction, heat, salt, alcohol, and formalin. It was found that the surface of the traumatized area, in each instance, was coated with an alkaline surface of pH 7-9.

This alkalinization of the surface after trauma was not affected by submucosal infiltration of local anesthetic. Also, total gastric pouches in stimulated and unstimulated dogs were filled with ethanol (50% and 70%). In stimulated animals, the gastric secretory output of vol. and acid were considerably reduced. In nonstimulated animals, there was a transient rise in the vol. of gastric juice after ethanol instillation followed by a reduced output. However, the conc. of acid was low after ethanol admin. It is suggested that part of the explanation for these findings lies in the effect of injury on the secreting epithelium, this effect being physiologic and not associated with gross structural damage to the secreting cells.

7818 EFFECTS OF INDUCED HYPERCALCEMIA ON HUMAN GASTRIC SECRETION. (E.) Barreras, R. F. (U. Wisconsin Med. Sch., Madison) and R. M. Donaldson, Jr. *Gastroenterology* 52(4):670-675, 1967.

Hypercalcemia was induced in 24 peptic ulcer patients by i.v. admin. of Ca hexonate (in 0.9% saline; rate of 4 mg Ca/kg/hr., 3 ml fluid/kg/hr.). Mg (in saline) was admin. at 0.4 mEq in the single hr. of infusion, with a fluid delivery as above. Betazole (1.5 mg/kg), atropine (0.6 mg) and pentolinium (15-20 mg) were all admin. s.c. Basal acid output was the acid output in the hr. following the initial discard period (15-min. collection intervals followed an initial discard collection of 20 min.). Peak acid output was the max. 30-min. period, expressed as an hourly rate. Serum Ca and Mg were measured by atomic absorption spectrophotometry. Pepsin was measured by the hemoglobin substrate method of Anson and Mirsky. Hypercalcemia led to a marked increase in gastric secretion. Acid output rose to 12.2 mEq/hr., a rate which was 29% of the peak response to betazole and 4.5 times the basal acid output. Pepsin output rose to a rate which was 43% of the peak betazole response. Hypercalcemia failed to produce a significant alteration in the peak response to betazole. The inj. of atropine or pentolinium abolished the effect of hypercalcemia on the spontaneous gastric secretion, as did the concomitant induction of hypermagnesemia.

7819 CRITICAL EVALUATION OF THE ASSESSMENT OF MAXIMAL GASTRIC SECRETION STIMULATED BY HISTAMINE. (E.) Royle, J. P. (St. Bartholomew's Hosp., London) and B. N. Catchpole. *Brit. J. Surg.* 54(1):56-63, 1967.

Gastric secretion studies were made on normals and patients with duodenal and benign gastric ulcers. After a 12-hr. fast, Ryle's tube (to which were attached 2 fine polyethylene tubes for gastric inj.), was passed, under X-ray monitoring, so that its tip lay on the greater curvature of the stomach to the left of the vertebral column. Gastric secretion was withdrawn from the main lumen of the Ryle's tube and air was inj. down the distally opening side tube at 25 ml/min. Resting secretion was collected for 30-40 min.; i.v. inj. of a mixed soln. of hista acid phosphate 0.04 mg/kg/hr. and mepyramine maleate 50 mg/hr. was made with a slow infusion pump while maintaining continuous aspiration an concomitant air inj. When a max. rate of secre tion was reached, an intragastric infusion of dye-marked saline or $NaHCO_3$ was made at a rate double the vol. of aspirate, or raise its pH to 3.3; infusion lasted for 30 min. but histamine stimulation with gastric aspiration continued until acidity of aspirates returned to preinfus levels, approx. 15 min. In the 67 patients, th acid conc. and vol. of aspirated secretions ros to a max. and plateaued. Acid recovery rose to a max. when conc. and vol. of recovered secr tions both reached a max., but time varied betw patients. Vol. reached a max. before acidity i 36, simultaneously in 17, afterwards in 14. Variation in acidity from sample to sample was less than 5% in 66; av. variation in vol. was 19%. There was some correlation between duoden pH changes and variation in vol. recovery. In saline infusion (9), the net vol. of secretion recovered was always less than that before sali infusion when histamine alone was inj.; in 5, the acid recovered was greater than with simple histamine inj. at its max., despite the reducti in net vol. recovered. In 6, the total amount of dye recovered from the stomach during and after inj. was 68-90%. In the bicarbonate infusion (34), the net vol. was lower than with histamine alone, in 32 being more than 10% lowe in 22; dye recovery in 19 was 60-97%. Continuo inj. of histamine and an antihistamine, rather than a single inj., permits the period of max. secretion to be recognized and measured whether it occurs early or late. Pooling of secretion in the stomach can be recognized when a prolong histamine stimulation is used. The possibility of intermittent or continuous pyloric loss of acid secretion, especially in hypermotile stoma which is present in any method of stimulation o gastric-secretion may result in a serious under estimate of secretory capacity. With continuou histamine inj. and intragastric titration by alkali, parietal cell output can be measured whether pyloric loss is occurring or not.

7820 HORMONAL STIMULATION OF NECTURUS GASTRIC MUCOSA *IN VITRO*. (E.) Shoemaker, R. L. (U. Alabama Med. Ctr., Birmingham) B. I. Hirschowitz and G. Sachs. *Amer. J. Physi* 212(5):1013-1016, 1967.

The mucosa (with muscle layers removed) of *Necturus* stomach was mounted in a modified Ussing flux chamber. The following were measur acid secretion, potential difference, short-circuit current and resistance. The nutrient soln. contained (in mmoles/liter): Na, 102; K, 4; Ca, 1.7; Mg, 0.8; Cl, 91; HCO_3, 18; HPO_4, 1; glucose, 10 mM. Secretory soln.: Na, 100; K, 4; Cl, 104. For Cl-free experiments, SO_4 was

tituted; for Na-free, choline. In 16 of 19
arations, no spontaneous secretion was obtained
he resting state, which was maintained in-
nitely. Addition of gastrin pentapeptide
^{8} M) or histamine (10^{-4} M) caused a stimula-
and onset of secretion, with a rise in
ntial difference and short-circuit current
a variable response in resistance. Max.
etion was obtained with 0.013 µg/ml gastrin.
tion of 10^{-7} M methacholine resulted in a
ntial difference spike. With secretion
blished by gastrin, methacholine resulted in
ansient spike of potential difference and a
in acid rate. Anoxia and SCN both suppressed
rate within 15 min., but only anoxia sup-
ssed the potential difference. Substitution
la by choline resulted in an inverted potential
ference dependent on maintained acid rate; SO_4
lacement of Cl resulted in a fall of potential
ference and zero acid rate. The differences
lecturus gastric mucosa from other *in vitro*
parations are stressed.

QUANTITATIVE EVALUATION OF INTRINSIC
FACTOR FOLLOWING STIMULATION OF THE
TRIC MUCOSA BY PROTEIN HYDROLYZATE. (It.)
a, S. (U. Bologna, Italy), F. Possati and
Fiore. *Haematologica* 51(11):897-904, 1966.

effects on gastric secretion of intrinsic
tor of the admin. by stomach tube of 50 ml
gelatin hydrolyzate (450 mg of a mixture of
no acids obtained by enzymatic hydrolysis of
atin and 450 mg of proteast) were studied in
ormal subjects and 1 patient with duodenal
er (6 men and 4 women; age 17-62 yr.). Samples
gastric juice were obtained every 15 min.
r a 1-hr. period following stimulation. Assay
intrinsic factor was performed according to
Aderman-Chanarin radioimmune method using
i-intrinsic factor antibodies, ^{58}CO-B_{12}, and
ivated charcoal. Total vol. of gastric juice
nged from 9-43 ml before, and 79-310 ml after,
imulation. Free acid content ranged from
00693-0.65 mEq/hr. before and 0.007-22.44
q/hr. after stimulation. Secretion of intrinsic
ctor ranged from 9.13-52.6 U/ml before and
.6-75.34 U/ml following stimulation. Standard
viation for intrinsic factor values before
imulation av. 588.2 ± 368.44, after stimulation
14 ± 4647.6. The above values pertain to
rmal subjects and indicate that protein
drolyzate increases both total acid and intrinsic
ctor secretion. In the patient with duodenal
cer, values of total vol. of gastric juice,
ee acid content, and intrinsic factor content
re 60 ml, 0.37 mEq/hr., and 38.62 U/ml, resp.,
fore stimulation and 259 ml, 4.67 mEq/hr., and
.6 U/ml, resp., after stimulation. No correla-
on was observed between free or total acid
d intrinsic factor. Secretion of intrinsic
ctor was highest in patients with higher basal
values, although a very high secretion was
served in a patient with basic pH, probably
ecause of abundant alkali duodenogastric
eflux.

7822 INFLUENCE OF SALINE DIURETICS ON GASTRIC SECRETION IN CARDIAC DECOMPENSATION. (It.) Piedimonte, L. (A. Cardarelli Civil Hosp., Campobasso, Italy). *Minerva Med.* 58(28):1219-1222, 1967.

The effects of a saline diuretic on gastric secretion were studied in 18 patients (10 men and 8 women) with decompensated heart disease and moderate-to-marked edema. Patients were subjected to the following tests at the time of hospitalization, 1 wk. later, and 2 wk. later (or less if dismissed earlier): "Gastrotest" for gastric acidity, urinary chlorides, body wt., urine vol. Patients were kept on low-salt diets and treated with hydrochlorothiazide (p.o.; daily dose not stated). Regression of edema was good-to-marked in 9 patients, slight-moderate in 8, and absent in 1. Increase in gastric acidity was good-marked in 8 patients, slight-moderate in 7, and not present in 1. Results seem to indicate that restoration of the blood supply in the wall of the stomach restores the vitality of the secretory cells enhancing their acid-secreting activity. The mechanism by which acid secretion of the stomach is increased by diuretics, such as hydrochlorothiazide, which inhibit carbonic anhydrase is discussed.

7823 STIMULATION OF SECRETING CELL MASS BY SUBMUCOSAL LYMPH FROM GASTRIC ANTRUM IN DOGS. (E.) Reynolds, B. L. (Radiat. Res. Ass., Dallas, Tex.). *Amer. Surg.* 33(4):352-358, 1967.

Stomachs of narcotized dogs were opened along the greater curvature from the pylorus to the esophageal inlet. Without removing the mucous covering, India ink was inj. into the antral submucosa. The antral region was perfused with alkaline soln. at pH 8. Within 20-30 min., the dye outlined vessels below the flat, non-folded antral mucosa, directed radially from the site of inj. towards the rugae-containing corpus or secreting cell mass; inj. was repeated in the fundus and direction was established towards the corpus. Direction of flow of submucosal lymph agreed with schemes of extrinsic drainage (Coller, Griffith). A second study used methyl orange in alkaline soln. (orange-yellow above pH 4.4, red below); the yellow soln. was inj. in the distal antral submucosa and immediately the distal half of antral mucosa was overlain with an alkaline soln. of NaOH at pH 8; within 15 min., red appeared at the mucosal surface of the antral-corpus margin and spread through the distal corpus; fundal inj. of methyl orange soln. followed by alkaline perfusion did not produce red coloration in the corpus. In histological sections from the India ink preparations, the dye extended from the submucosa to the mucosa, between the gastric glands, clearly demonstrating the presence of dye in the interstitial tissue, if not in the lymph channels. Using extremity cannulation and alkaline perfusion of the open antrum, approx. 5.0 ml of submucosal fluid was collected from 10 dogs. This was inj. into the left ventricle of a dog with a Heidenhain and a main gastric pouch. Acid response from the pouches occurred within 3-5 min., with a peak at 10 min. An intrinsic gastric mechanism for secretory control is proposed, with the suggestion that extragastric neuronal, glandular, and vascular substances modify such control.

7824 GASTRIC ACID OUTPUT AND CIRCULATING ANTI-BOVINE SERUM ALBUMIN IN ADULTS. (E.) Kraft, S. C. (Scripps Clin., LaJolla, Calif.), R. M. Rothberg, C. M. Knauer, A. C. Svoboda, Jr., L. S. Monroe and R. S. Farr. Clin. Exp. Immun. 2(3):321-330, 1967.

Analysis of acid secretion was made in 241 gastrointestinal patients (16-84 yr., av. 48.2) as part of a complete gastrointestinal study or as control values for an unrelated study. Augmented histamine tests were performed (Kay). Fasting gastric contents were discarded and four 15-min. basal specimens were collected by intermittent suction. Saliva was removed by constant dental suction. After the second 15-min. sample, 100 mg diphenhydramine HCl was inj. s.c. After the fourth specimen, 0.4 mg/kg histamine phosphate was inj. s.c. and 4 more 15-min. samples were collected. A fasting venous blood sample was taken at time of each gastric analysis, sera were stored at -20° C and studied in duplicate for antibovine serum albumin (Barrick and Farr). In those 16-40 yr. old (71), the percentage of high, normal, and low acid secretors with antibovine serum albumin were 13%, 29%, and 13%, resp., while in those above 41 (171), they were 34%, 22%, and 15%. Further demonstration of the relationship between high gastric acid and high antibovine serum albumin was given by consideration of gastroduodenal disease and history of allergy. There was no correlation between the quantity and immunoglobin classes of antibovine serum albumin and the differences in gastric output or dietary history. Antibovine serum albumin activity could not be demonstrated in any of the 16 patients denying recent intake of bovine serum albumin. It is suggested that gastric acidity is one of many variables on which the capacity to maintain or reinitiate antibovine serum albumin production is dependent.

7825 EFFECT OF GASTRIN AND GASTRIC DISTENSION ON GASTRIC AND PANCREATIC SECRETION IN THE RAT. (E.) Chaitman, B. (McGill U., Montreal, Canada) and R. M. Preshaw. Canad. J. Physiol. Pharmacol. 45(3):558-561, 1967.

Rats were fasted for 24 hr. and under ether the common bile duct was cannulated with polyethylene tubing (external diameter 1.0 mm) and ligated just below the hepatic hilus. A flanged polyethylene tube (external diameter 6.2 mm) was tied into the forestomach to form a gastric fistula, and the pylorus ligated. The external jugular vein was cannulated with polyethylene tubing (external diameter 1.0 mm), connected to a constant infusion pump, and perfused with 0.15 M NaCl at 3 ml/hr. Experiments were performed on the third postoperative day. Gastric and pancreatic juice were collected hourly by gravity drainage. The latter was collected into tared microtubes and wt. of juice used to estimate flow rate. Gastric acid was measured by titration with NaOH. Pancreatic protein conc. was measured spectrophotometrically against bovine serum albumin. Pancreatic protein output can be used as an index of total enzyme output since the protein content of pancreatic juice is almost entirely enzymatic. Gastrin was admin. at 4 dose levels (0, 8, 16, 32 Leo U) by single i.v. inj. at 2-hr. intervals. A baseline collection was made 1 hr. before inj. and results were expressed as per cent of basal response. Controls received an equivalent vol. of saline i.v. In other experiments a Latex balloon was introduced into the stomach through the gastric fistula and connected to a vertical glass tube containing water to a height of 15 cm above the animal. Commercial (Leo) and prepared (after Gregory and Tracy) gastrin caused similar increases in gastric acid and pancreatic protein output, but neither produced a change in pancreatic flow rate. Control experiments showed that rates of gastric and pancreatic secretion were fairly constant. This confirms that gastrin is an effective stimulant of gastric acid secretion in the conscious rat. Extract of secretin caused an increase in pancreatic flow rate and protein output and a decrease in gastric acid secretion. The experimental pancreas was capable of responding with an increase in flow rate after an appropriate stimulus. This suggests that gastrin had no effect on flow rate. Gastric distention caused a small increase in gastric acid output and a transient rise in pancreatic protein output. Gastrin-induced stimulation of acid secretion and pancreatic protein output suggests that a gastric phase of pancreatic secretion exists in rats.

7826 THE FINE STRUCTURE OF GASTRIC EPITHELIAL CELLS IN THE SUCKLING RABBIT WITH PARTICULAR REFERENCE TO THE PARIETAL CELL. (E.) Hayward, A. F. (Roy. Dent. Hosp., London). Z. Zellforsch. 78(4):474-483, 1967.

A small segment of fundus of stomach was excised from rabbits at the following stages: before feeding with no milk present in stomach; 6 hr. after birth, stomach distended with semifluid milk; on the second and fifth postnatal days. Specimens were fixed in buffered 1% osmium tetroxide; embedded in Araldite; thin sections examined by electron microscopy. pH of stomach contents and mucosal surface was measured with indicator paper. Immediately after birth, before feeding, the stomach contained a greenish mucous fluid and gas bubbles. At later stages, stomach contents consisted of partially clotted milk. pH of stomach contents was approx. 7, of

l surface 2-3. There was a reduction in
and change in distribution of smooth cyto-
c vesicles of gastric parietal cells of
n rabbits in comparison to those of the
erm fetus. The apical surface and intra-
ar canaliculus were more complex. It is
ted that these changes are indicative of
set of acid secretion. The remaining
l and submucosal connective tissue cells
l dilatation of endoplasmic reticulum and
lation of fat. By 5 days after birth, the
ecture of individual cells resembled that
lt cells.

EFFECT OF EXCLUSION OF BILE FROM THE INTESTINE ON GASTRIC ACID SECRETION.

Nahrwold, D. L. (VA Ctr., Los Angeles,
) and M. I. Grossman. Gastroenterology
:667-669, 1967.

dogs were prepared with a Heidenhain pouch
ed by a Gregory cannula, cholecystectomy,
Thomas cannula inserted into the duodenum
ite the opening of the common bile duct.
mized tests began 3 wk. after operation.
sts without diversion of bile to the exterior,
uodenal cannula was not opened. In "diver-
tests, the cannula was opened and a poly-
ene tube inserted about 5 cm into the common
and brought out through a small hole in a
inserted into the duodenal cannula to prevent
ge of duodenal contents. Experiments began
is time. Gastric juice was collected con-
usly from the Heidenhain pouch in 15-min.
es; vol. and acid conc. were determined;
was collected continuously in 15-min.
es and vol. measured. In all tests, 80 g of
rated dog food was given after collection
sal gastric secretion for either 1 or 3 hr.
ntire series of tests was repeated except
75 U of secretin was admin. i.v. 1 hr. after
ng when the gastric secretory response was
near peak. When bile was not excluded from
ntestine, secretory responses from the
nhain pouches were the same in 1- and 3-hr.
gastric juice collection tests. When food
iven 1 hr. after cannulation of the common
the acid secretory response was not signifi-
y different from tests without exclusion of
; when food was given after 3 hr., the gastric
tory response was markedly lower than after
(differences in acid output were significant
nning 30 min. after feeding). Secretin (1
after feeding) inhibited gastric acid secre-
, stimulated by a meal, to the same degree
bile was excluded as when it was not. The
ence of bile in the intestine is a factor
n contributes to the regulation of gastric
etion; inhibition of gastric secretion by
etin is unaltered by removal of this factor.

STUDIES OF RESTING ISOLATED FROG GASTRIC MUCOSA. (E.)

Kasbekar, D. K.
California Sch. Med., San Francisco). Proc.
Exp. Biol. Med. 125(1):267-271, 1967.

Mucosae of Rana catesbeiana, stripped from their smooth muscle, were mounted between chambers (by the Durbin technic), and all stomachs, 2.85 cm^2 in area, were incubated overnight in 14 ml each of histamine-free nutrient soln. on the submucosal side and 120 mM NaCl on the luminal side. The nutrient soln. was bubbled with a gas mixture containing 95% O_2-5% CO_2, and the secretory soln. with 100% O_2. Both the nutrient and NaCl soln. used in overnight studies contained 1 mg/ml each of streptomycin and penicillin. The acid secretory rate of mucosa incubated with histamine-free media decreased to a very low rate after approx. 16 hr., the potential difference increased and the short-circuit current declined. The addition of 10^{-4} M histamine to the nutrient medium bathing the serosal side restored acid secretion to approx. 80% of the initial rate; there was little change in potential difference and there was an increase in short-circuit current. No difference existed in the ATPase activity of the resting and histamine-stimulated mucosa; the ATP level of the stimulated mucosa, however, was slightly greater that that of the resting mucosa. The procedure of preincubation of the mucosa in histamine-free media has made it possible for the first time to reproducibly obtain resting mucosae which can be stimulated by added histamine.

7829 STUDIES OF GASTRIC HYDROCHLORIC ACID SECRETION IN PERNICIOUS ANEMIA: THE VALUE OF NEAR-MAXIMAL STIMULATION TECHNICS. (E.)

Wenger, J. (Emory U. Sch. Med., Atlanta, Ga.), I. Backerman, J. Steinberg and B. R. Gendel. Amer. J. Med. Sci. 253(5):539-548, 1967.

A total of 54 patients with megaloblastic anemia were studied using near-max. stimulation of gastric acid secretion. Most were previously diagnosed as pernicious anemia by standard criteria, including the Schilling test. Others were current patients under investigation because of a megaloblastic anemia. Gastric stimuli used included reserpine HCl (1.0 mg admin. i.v. over a 30-min. period), betazole (0.5 mg/kg, after completion of the reserpine test) and histamine phosphate (0.04 mg/kg admin. s.c. for 30 min. after the admin. of 50 mg of diphenhydramine i.v.). Combined reserpine and betazole was used on 30 subjects, and 24 were tested with the augmented histamine test. A new criterion for achlorhydria was defined as the failure of gastric pH to fall 1.0 U or more, or the failure of gastric pH to fall below pH 6.0 when stronger stimuli were used. By these criteria 3 of 54 patients were found to secrete acid. Subsequent study showed that 2 of these had gastric intrinsic factor and therefore did not have pernicious anemia. Diagnosis in these 3 patients were non-tropical sprue, nutritional megaloblastic anemia and (probable) juvenile pernicious anemia. This study supports the concept that the secretion of HCl is an unusual finding in adult patients with pernicious anemia. It was also shown that the study of gastric acid secretion using a near-max. stimulus and including measurements of the gastric juice pH obtained is a very useful procedure in the study of a patient with pernicious anemia. The case histories of the 3 acid-secreting patients are described in detail.

7830 EFFECTS OF A SPECIFIC GASTRIN ANTAGONIST ON GASTRIC ACID SECRETION IN POUCH DOGS.

(E.) Bedi, B. S. (Western Infirm., Glasgow, Scotland), G. Gillespie and I. E. Gillespie. *Lancet* 1(7502):1240-1243, 1967.

The action of antigastrin, 2-phenyl-2-(2-pyridyl) thioacetamide, on the gastric acid responses in pouch dogs was studied; 3 dogs had vagally innervated pouches separated from the main gastric remnant by a double mucosal bridge and drained by a Gregory-type cannula, and 3 other dogs had Heidenhain-type vagally denervated pouches. The effects of antigastrin, given as single i.v. inj., were tested against gastric acid responses to the continuous constant-rate i.v. infusion of pentagastrin, pure gastrin II, histamine and the stable choline ester, methacholine; in addition, the effects of single i.v. inj. of antigastrin on the response to a standard meal were also studied. Antigastrin specifically inhibited the gastric secretory responses to both pure gastrin II and the synthetic gastrin-like polypeptide, pentagastrin. The agent had no effect on responses to histamine or methacholine. Antigastrin partially suppressed the gastric acid response to a meat meal in vagally innervated pouch dogs, and almost completely abolished the Heidenhain-pouch response to the meal. Since it is generally accepted that the meal response of the Heidenhain pouch is almost wholly mediated by gastrin release (whereas the control of acid secretion in the innervated pouch contains both vagal and gastrin components), this difference in the inhibitor behavior of the 2 pouches is additional support for the specific activity of antigastrin against gastrin-stimulated acid secretion. Propylene glycol had to be used to dissolve antigastrin, and it is advised that further control experiments with this organic solvent are necessary. The effective dose of antigastrin appeared to be 10 mg, but further, complete dose-response studies must still be done.

7831 EFFECT OF SECRETIN ON BICARBONATE SECRETION IN FLUID PERFUSING THE RAT ILEUM.

(E.) Hubel, K. A. (U. Iowa, Iowa City). *Experientia* 23(5):337-338, 1967.

The terminal 25 cm of small intestine in Sprague-Dawley rats of either sex was perfused with a soln. which contained the following components: NaCl, 102.8 mM/liter, KCl, 4.7 mM/liter, KH_2PO_4, 0.8 mM/liter $NaHCO_3$, 28.2 mM/liter, $MgCl_2 \cdot H_2O$, 1.2 mM/liter, glucose, 16.7 mM/liter and polyethylene glycol, 2 g/liter. The influence of i.v. secretin was determined by comparing the net electrolyte fluxes in the period after secretin admin. with those in the alternate period after i.v. saline. In Group 1, saline was inj. 5 min. after beginning the first perfusion period and secretin was inj. 5 min. after the start of the second. In Group 2, inj. were given in reverse order. Electrolyte fluxes determined were bicarbonate, Cl, Na and K. Single large i.v. doses of secretin failed to influence the net fluxes of any of the electrolytes in fluid perf ing the rat ileum. These results suggest that bicarbonate secretion in the ileum is controlle by a mechanism which differs from that of the pancreas and biliary tree.

7832 SECRETORY RATE OF GASTRIC ACID AND PANCREATIC BICARBONATE IN THE DOG AFTE FEEDING.

(E.) Rune, S. J. (U. Copenhagen, Denmark) and F. W. Henriksen. *Gastroenterology* 52(6):930-939, 1967.

The indirect method of estimating the rate of gastric acid secretion after a solid meal (450 g of lumps of raw or boiled pork heart, free fr any visible fat) was applied to 4 mongrel dogs, in which pancreatic juice was collected directly from the pancreatic duct. In all feeding experiments the meal gave rise to an increase in the blood buffer-base conc. without any discernible time lag. The rate of acid secretion during the first 30 min. after a meat meal was found to be the same as during the first 30 min. of a max. i.v. histamine infusion test; from this it was concluded that the two modes of stimulation are of equal intensity. The means of the secretory rates during stimulation with food and with histamine were, resp., 33 mEq/hr. and 31 mEq/hr. The pancreatic response was seen within 5 min. after the meal, with a peak bicarbonate output in the second or third 10-min. period. The pancreatic bicarbonate secretion in the first 30 min. after the meal was highly correlated with the gastric acid output in the same period, whil the ratio between the two secretions on an equivalent basis was: gastric acid to pancreatic bicarbonate = 6:1. No significant acid or base loss from the gastrointestinal tract other than the secretion of gastric acid and pancreatic bicarbonate was provoked in the early postprandi period.

7833 INHIBITION OF GASTRIC MUCOUS SECRETION BY ACTH. AN EXPERIMENTAL STUDY.

(E.) Desbaillets, L. (U. Chicago Sch. Med., Ill.) and R. Menguy. *Amer. J. Dig. Dis.* 12(6):582-586, 1967.

Dogs were prepared with vagally denervated antra pouches, and the rate of secretion and the biochemical composition of mucus secreted by the gastric antrum were studied before and during admin. of ACTH (5 U/kg). In 5 of 6 dogs the admin. of ACTH was accompanied by a decrease in mucus secretion, which ranged from 15-43% of control values. The overall change in the biochemical composition of the mucus secreted durin ACTH admin. was expressed as a decrease in the carbohydrate (total): protein ratio in the dry

substance. The conc. of sialic acid decreased
of 6 animals, L-fucose in 3 of 6, hexosamines
of 6 and hexoses in 4 of 6 animals. These
lts suggest that ACTH decreases the rate of
ric secretion of mucus and alters the composi-
of mucus in such a way that it may be more
ily digested; ulceration during admin. of
and during stress may be due to impaired
sal defense mechanisms.

INJECTION OF 5% PHENOL INTO SUBMUCOSA OF DENERVATED GASTRIC POUCH. (E.)

piro, H. (U. Tennessee Sch. Med. U., Memphis)
L. G. Britt. *Arch. Surg.* (*Chicago*) 94(6):
844, 1967.

dogs were prepared with denervated gastric
hes; after control values for total acid
ut were established for 0.1 and 1.0 mg (base)
istamine and for 200 and 400 g of dog food,
gastric pouches were exposed at laparotomy
5% phenol soln. was inj. throughout the
ucosa of each pouch. After a 4-5 wk. recovery
od, the gastric pouch was stimulated as before,
repeated at intervals up to 5 mo. In 2 animals,
ly denervated gastric pouches were constructed
5% phenol was inj. throughout the submucosal
on of 1 of each pair of pouches. These dogs
allowed 5-6 wk. to recover, and then gastric
e was stimulated with 0.1 and 1.0 mg (base)
istamine and 200 g of dog food; the studies
repeated at intervals up to 5 mo. In the
t group of animals, the gastric secretory
onse to 0.1 mg of histamine base was depressed
3%, and the gastric secretory response to
mg of histamine base was reduced 54-96%.
ric secretory response to 200 g of dog food
depressed 82-93%, and that to 400 g of food,
4%. In the 2 dogs with doubly denervated
ric pouches, gastric secretory response to
mg of histamine base in the phenolized pouches
depressed 86-91%, and that to 1.0 mg of
tamine base was reduced 81-87%. In these same
ches, the gastric secretory response to 200 g
dog food was depressed 62-80%. In both groups,
nolization of the submucosa did not reduce
number of parietal cells or change the
tological appearance of the gastric tissue.
ctivity of the parietal cell was not constant
it is assumed that acid secretion may be
irely blocked by a functional inhibition of
otherwise intact parietal cells. These experi-
ts suggest that the submucosal plexus of
ssner may be important in the control of the
ietal cell.

5 INSULIN DEPRESSION OF HUMAN GASTRIC SECRETION. (E.)

Schapiro, H. (U.
nessee Sch. Med., Memphis), A. J. Cummins and
D. Wruble. *Arch. Surg.* (*Chicago*) 94(6):881-
, 1967.

e effect of insulin on gastric secretion was
udied in 10 groups of patients composed of 69
jects; there were 11 controls, 20 with duodenal ulcer, 5 with subtotal gastrectomy (antrectomy), 4 with bilateral adrenalectomy, 6 with bilateral oophorectomy, 5 with bilateral orchiectomy, 3 with pancreatitis, 5 with diabetes mellitus, 3 with total thyroidectomy and 7 with bilateral thoracolumbar sympathectomy. After a 2-hr. basal period, 0.25 U/kg insulin was admin. i.v., and gastric juice was again collected for 3 additional hr. There was an inhibition of gastric secretory vol. in all patients; this inhibition began within 15 min. and lasted 15-45 min. In only a few cases was the acid conc. decreased. A decrease in total acid output was noted in every case. Neither the time of onset of inhibition nor the duration of the inhibition varied significantly between controls and those with duodenal ulcer, but there was a greater inhibition of gastric secretion in the ulcer group. In controls, total acid output before insulin av. 0.23 mEq/15 min. and after insulin, 0.09 mEq/15 min.; in duodenal ulcer patients, preinsulin values av. 0.71 mEq/15 min. and postinsulin values av. 0.13 mEq/15 min. The other groups had mean preinsulin values which ranged from 0.10-0.26 mEq/15 min., and mean postinsulin values which ranged from 0.04-0.13 mEq/15 min. Although the decrease in duodenal ulcer patients was greater, the ultimate total acid output was similar in all groups, thereby indicating that the final value was independent of the preinsulin total acid value. At the end of the period of inhibition, a phase of gastric hypersecretion began that lasted 2-3 hr. in all patients; both the vol. and conc. of acid were increased during this period of hypersecretion. It was not possible to postulate the exact mechanism of action of insulin in inhibiting gastric secretion.

7836 GASTRIC SECRETION DURING PREGNANCY AND LACTATION IN THE RAT. (E.)

Lilja, B. (U. Lund, Sweden) and S. E. Svensson. *J. Physiol.* (*London*) 190(2):261-272, 1967.

Gastric acid secretion was studied in female rats before, during and after pregnancy using different types of stomach preparation (whole-stomach fistula and denervated gastric pouch). During the same periods the histamine-forming capacity was determined in gastric mucosa and mammary gland. Gastrin, "Gastrin II" and histamine were used to stimulate secretion. In response to a test meal (a semisynthetic, histamine-free regimen), secretory responses to histamine or gastrin were unchanged or slightly increased during the first 2 wk. of pregnancy, while there was a decrease during the third wk.; the same pattern was noted in all pregnant rats. In rats with a whole stomach fistula, interdigestive acid secretion was increased during pregnancy and lactation. In rats with a denervated chronic pouch, secretory response to stimulation with gastrin and histamine was augmented during pregnancy and lactation. The histamine-forming capacity of the gastric mucosa was increased 2-3 fold during the final days of pregnancy and also during lactation. Histamine-forming capacity of the mammary gland was increased 2-3 fold during lactation as compared with the fully developed gland in pregnancy.

7837 RELATIONSHIP OF MAST CELL POPULATION AND ENDOGENOUS HISTAMINE CONCENTRATION IN THE CANINE STOMACH.

(E.) Molina, E. (U. Minnesota Med. Sch., Minneapolis), W. P. Ritchie, Jr., D. Grigg and W. H. Wangensteen. Proc. Soc. Exp. Biol. Med. 125(1):71-73, 1967.

The distribution of histamine and mast cells was assayed in the fundic, corporal and antral mucosa of the dog stomach; 12 areas from each of 4 stomachs were studied. Mast cell profiles of these areas showed the cell population to be similar in all mucosal areas, but the greatest number of cells occurred deeper in the glandular mucosa of the antrum than in the glandular mucosa of the fundus and corpus. In contrast to this, the amount of histamine in the antral mucosa (73.3 ± 4.9 µg/g) was roughly 50% of that noted in fundic and corporal mucosa (133.6 ± 1.4 µg/g); this difference was statistically significant. Proposed as an explanation of these findings is the hypothesis that there may exist a dual pattern of histamine storage in the gastric mucosa, i.e., the histamine present in the antrum may be bound to mast cells while the major portion of corporal and fundic histamine is more closely associated with the secretory cells themselves, possible bound by mucin.

7838 MORPHO-PHYSIOLOGICAL PROPERTIES OF GLANDS RELEASING HYPOTONIC SECRETIONS.

(Rus.) Krestinskaia, T. V. (Sechenov Inst. Evolutionary Physiol. and Biochem., Leningrad, USSR). Biull. Eksp. Biol. Med. 62(12):21-24, 1966.

Submaxillary and sublingual salivary glands, the spleen, and mammary glands of mature albino rats, as well as parotid glands of 6, 14 and 20-day-old puppies were analyzed histochemically. Acid mucopolysaccharides were found in the basic substance of the connective tissue membrane of interlobular ducts and especially in the basal membranes of salivary tubules. Acid mucopolysaccharides were absent from basal alveolar membrane and interpolar portions. The dehydration of succinic and α-ketoglutaric acids was most marked in the duct cells; dehydration of succinic acid was especially marked in cells of the salivary tubules. These enzymes were almost totally absent in alveolar cells and intrapolar portions. The intensity of dehydration of malic and isocitric acids in the cells of alveoli and ducts was similar and relatively small. The activity of succinic dehydrogenase in 6-day-old puppies, which at that time had no differentiated salivary tubules, was very low; at this time their saliva was isotonic with blood plasma. Hypotonic saliva appeared by the second wk. after birth, at which time differentiation of the salivary tubules was clear and enzymatic activity markedly increased. In spleen and mammary glands the acid mucopolysaccharides were found in the basic substance o
the connective tissue stroma in slight amount; they were absent in the basal membranes of the secretory portions and ducts. Dehydrogenase activity was similar in the alveolar and duct cells. In the spleen the intensity of dehydration, including succinic acid, was low, while i
mammary glands the activity of the latter was quite high.

7839 EFFECT OF FLOW RATE ON PAROTID FLUID CALCIUM, MAGNESIUM AND PROTEIN CONCENTRATIONS IN THE HUMAN.

(E.) Windeler, A. S. (Brooks Air Force Base, Texas) and I. L. Shanno
US Air Force Sch. Aerospace Med. SAM-TR-67-18: 1-5, 1967.

A vacuum-type metal collecting device was place
(with minimal manipulation) over the orifice of
the right Stensen's gland in 23 resting males (18-23 yr.) to obtain an unstimulated 2.0 ml sample. Each then gave 7 more samples in respo
to exogenous stimulation (in order): 0.2%, 0.4%, 0.8% citric acid; sour fruit drop; 0.8%, 0.4%, 0.2% citric acid. Acid was admin. by retention of 2.5 ml in the mouth without swallo
ing for 30 sec. After expectoration, swallowin
was permitted after a 30-sec. waiting period, t
whole procedure being repeated until 3.0 ml flu
was obtained. Test collection with each stimul
was preceded by a 5-min. waste sample to permit the gland to adapt and the device to clear. Ca
Mg and protein were measured and expressed as wt./vol., and a secretion rate was calculated, wt./time. Values for none and 7 exogenous stimulants were: flow rate (ml/min.), .036, .1
.42, .66, 1.1, .62, .51, .35; Ca (mg/100 ml),
4.46, 2.50, 2.56, 3.00, 3.78, 3.22, 2.86, 2.56;
Mg (mg/100 ml), .427, .085, .054, .044, .037,
.049, .057, .060; total protein (mg/100 ml), 34
182, 186, 223, 273, 237, 205, 207. A positive correlation existed between flow rate and Ca conc., and this increased when Ca was expressed in µg/min. Both values were significant and significant differences were found in coefficie
for different subjects. Mg conc. was negativel
correlated and variance in coefficients between subjects was insignificant. When Mg was calcul
ted in µg/min., the correlation was positive an
differences between subjects was significant. Protein conc. was positively related to flow rate and responses varied significantly between subjects. Mg conc. was negatively correlated with protein and responses varied significantly between subjects. Ca was positively related to protein, but there were significant differences between subjects. In view of inconsistencies between persons, one cannot predict with reliab
ity, an individual's Ca and protein conc. at a given flow rate.

7840 SECRETORY RESPONSES AND CHOLINE ACETYLASE OF THE RAT'S SUBMAXILLARY GLAND AFTER DUCT LIGATION.

(E.) Ohlin, P.

Lung, Sweden) and C. Perec. Experientia
):248-249, 1967.

right submaxillary duct was ligated in 28
le rats. Secretory responses to sialagogues
determined (1-4 wk. after ligation) in 15,
holine acetylase in 13. Rats were anesthetized,
axillary ducts cannulated. Amount of saliva
aring at the cannula tip was observed after
inj. of epinephrine (20 µg/kg), metacholine
µg/kg) and pilocarpine in increasing doses
m 50-1000 µg/kg) every 30-60 sec. until max.
retory response was reached. Choline acetylase
ivity in gland was determined 1 wk. after
ation. Gland wt. was markedly decreased after
ation (97 to 80 mg). Secretory response to
ephrine was 1 1/2 drops of saliva from
trols, and this decreased gradually for 6 days
er ligation until no secretion was observed.
trol values for methacholine were the same,
zero secretion was reached in 3 days. Max.
rate of control gland (4 drops/min.) to
ocarpine (total 1-5 mg) was decreased to less
n 1 drop/10-15 min. after ligation. One wk.
er ligation, the total enzyme activity was
iar in control and ligated glands, but enzyme
c. increased from 300-600 µg acetylcholine/hr./g
tone powder, corresponding to the decrease in
nd wt. Ligation atrophy of the submaxillary
nd is probably not due to changes in parasym-
hetic secretory neurones, since the activity
choline acetylase was unchanged after ligation
the duct.

1 SECRETION OF CALCIUM BY THE SALIVARY
GLANDS IN THE DOG. (E.) Bazerque,
M. (U. Buenos Aires Sch. Med. & Dent.,
entina), W. F. Neuman and E. J. Miller. J.
t. Res. 46(2):446-451, 1967.

e dogs received water only for 24 hr., then
e anesthetized with Na pentobarbital: sub-
illary and parotid ducts were exposed and
nulated with 4-5 cm polyethylene tubing
ternal diameter 0.028-0.038 cm). Salivation
stimulated electrically or by i.v. inj. of
ocarpine in various doses. Ca in serum, in
otid and submaxillary saliva, in both salivary
sues, and in ultrafiltrates of saliva and
rum was determined by fluorescent ethylene-
minetetraacetic acid titration. Ca conc. was
5 times higher in parotid saliva (7.3 mEq) than
serum (4.8). This was paralleled in ultra-
ltrates (parotid, 6.0; serum, 315), indicating
at the parotid was capable of concentrating
trafiltrable Ca. Values in submaxillary saliva
hole sample 4.6; ultrafiltrate 3.8) were
milar to serum. Tissue samples of glands were
ken before and after drug stimulation. Stimula-
on decreased Ca conc. by a third in the parotid
efore, 9.0; after, 6.4) and by half in the
bmaxillary (39.7; 20.0). After max. drug
imulation, salivary Ca conc. decreased with
me (av. 7.9 mEq/liter for the first 5 min.;
8 at 42 min.). With the use of radioactive
Ca-^{2}P, specific activity (cpm/mg Ca) varied with intensity of stimulation. At 8 mg/kg, whether ^{45}Ca was inj. (i.v. or i.p.) 15-30 min. before or 15 min. after stimulation of salivation, the specific activity of parotid saliva was similar to serum. At a dose of 0.3 mg/kg, there was a delay of more than 1 hr. before parotid saliva levels equalled those in serum. Specific activity of parotid Ca was constantly lower than that of serum or saliva, and reached a max. of 60% of serum values at 1-2 hr. after inj. of ^{45}Ca. In stop-flow experiments the cannula was clamped with a hemostat, and flow from the contralateral gland continued normally; after 2 min., the flow in the clamped cannula was reinstated and samples were collected at measured intervals. There was a decrease in specific activity and increase in Ca conc. in the first sample after resumption of flow. The opposite obtained in the contralateral side used as control. This suggests a greater participation of Ca stored in the gland, which has a lower specific activity than serum Ca.

7842 EFFECTS OF ISOPRENALINE TREATMENT ON SECRETORY RESPONSES AND RESPIRATORY ENZYMES OF THE SUBMAXILLARY GLAND OF THE RAT. (E.) Ohlin, P. (U. Lund, Sweden). J. Oral Ther. 3(3):190-193, 1966.

Of 36 rats receiving isoprenaline (7.5 mg in 0.2 ml saline) i.p. twice daily for 1 wk., 22 survived and were experimented on 48 hr. after the last inj. To estimate secretory response, rats were anesthetized and the submaxillary duct exposed and cannulated with a fine glass cannula. A series of doses of epinephrine (0.2-20 µg/kg), methacholine (0.02-10), and acetylcholine (0.02-20) were inj. i.v. to determine threshold doses and the secretory responses to above-threshold doses, recorded on a smoked drum. To estimate max. secretory response, pilocarpine was inj. i.v. every 30-60 sec., starting with 50 µg/kg and later at 100-200 µg/kg, until a max. flow rate was reached, usually 15 min. after a total dose of 3 mg/kg. Max. secretory response was expressed in µliter/min./gland or µliter/min./mg gland tissue (dry wt.). Treatment with isoprenaline caused a significant increase in both dry wt. (41.5 to 133 mg) and wet wt. (163 to 470 mg) of gland. With 9 control glands, threshold doses were: acetylcholine, 0.5-2.0; methacholine, 0.1-1.0; epinephrine, 0.0-2.0 µg/kg. After treatment, threshold doses of the first 2 decreased slightly (to below 0.5 and 0.1 µg/kg, resp., in 50% of rats) while that for epinephrine decreased (to 0.2-0.5 µg/kg) in 5 of 6. The effect of treatment on secretory response to above-threshold doses was best seen in estimation of max. secretory response to pilocarpine. Values per gland were 19 µliter/min. in controls and 16 in treated, essentially unchanged after pronounced gland enlargement. When calculated per U wt., values decreased significantly from 0.46 to 0.14 µliter/min./mg. With isoprenaline; total activity of succinic dehydrogenase increased 71%, although the conc. decreased 40%; activity of the fumarase and cytochrome oxidase remained constant, while the conc. of both decreased 60%. Increased sensitivity of the gland after isoprenaline, may be partly due to a retention of isoprenaline in subliminal conc.

7843 A MICROREFRACTOMETRIC STUDY OF THE SALIVARY GLANDS OF THE RAT AFTER LIGATION OF THE EXCRETORY DUCTS. (E.) Gerzeli, G. (U. Pavia, Italy) and E. Mira. Acta Anat. (Basel) 65(1-3):256-274, 1966.

The excretory ducts of the right submaxillary and sublingual glands of 9 adult albino rats were ligated under ether anesthesia while the left glands were used as controls. The dry mass of single cellular elements of the glands were studied 12, 24, and 36 days after ligation using microrefractometric technics. Cryostat sections unfixed or fixed in formalin or ethanol were observed with a Leitz interference microscope using glycerine or distilled water as the immersion medium. Ligation of the ducts produced characteristic modifications of the protoplasmic fractions, definable by their behavior with regard to histological fixation and washing with water during the course of atrophy over the 36-day period. In particular, 12 days after ligation, was the presence of an important protoplasmic fraction labile to fixation and washing. In the successive periods this fraction was reduced in the specific secreting elements in a much more distinct way than in the striated excretory ducts.

7844 METRECAL-INDUCED CHANGES IN HUMAN SALIVA. (E.) Hall, H. D. (U. Alabama Med. Ctr., Birmingham), J. J. Merig, Jr. and C. A. Schneyer. Proc. Soc. Exp. Biol. Med. 124(2):532-536, 1967.

Parotid and submaxillary saliva was collected from 8 male dental students at 8:00 in the morning following 8-10 hr. of abstinence from eating, drinking and smoking. Pilocarpine (0.1 mg/kg i.m.) was used as a stimulant. Two determinations were made on each subject, the first preceding a wk. when only liquid Metrecal and water were eaten. After the first wk. saliva was collected and a normal diet eaten for 1 wk. when saliva was again collected. A marked reduction in vol. and total protein and amylase content of parotid saliva occurred following a wk. of a Metrecal diet. Restriction of solid food caloric intake (900 calories/day) resulted in wt. loss, but saliva vol., amylase, and total protein did not differ from the values collected on an unrestricted solid diet. These changes in the functional status of the parotid gland in man are attributed to a reduction in the masticatory and, therefore, in the reflexly-mediated secretory stimuli to the gland. Submaxillary secretion was unaffected by the Metrecal treatment, possibly due to the difference in innervation.

7845 AN IN VITRO PREPARATION OF DOG PAROTID GLAND. (E.) Tanzer, J. M. (Nat. Inst. Dent. Res., NIH, Bethesda, Md.). Proc. Soc.
Biol. Med. 124(3):912-915, 1967.

Parotid glands excised from young pentobarbit
anesthetized dogs were diced and washed in Kr
Ringer soln. containing 200 mg% glucose at pH
7.4. The tissue was then placed in a similar
containing 400 mg% collagenase and shaken for
hr. at 25-27° C. The reduced tissue was wash
three times with fresh Krebs-Ringer soln. wit
glucose. The tissue's ability to conc. iodid
was investigated at the same time distributio
inulin was studied by incubation of washed ti
in Krebs-Ringer glucose soln. containing 0.9
μc/10 ml Na ^{131}I and 500 mg% inulin. Under a
conditions a corrected wet tissue/medium ^{131}I
ratio of 1.75 was observed showing accumulati
of isotope. Inulin space av. 49.3%. Anaerob
incubation reduced wet tissue/medium ^{131}I rat
to 1.04, inulin space of 49.3%. 10^{-3} NaCN fu
inhibited ^{131}I uptake producing a ratio of 0.
and an inulin space of 51.8%. The inulin spa
values for the 3 conditions were not signific
different. It is concluded that accumulation
131I by the preparation is depressed by anaer
sis and obliterated by cyanide. It is sugges
that this in vitro preparation might prove us
in the soln. of major issues in exocrine glan
physiology.

7846 A MICROPERFUSION INVESTIGATION OF S
RESORPTION AND POTASSIUM SECRETION
THE MAIN EXCRETORY DUCT OF THE RAT SUBMAXILLA
GLAND. (E.) Young, J. A. (Free U. Berlin),
E. Frömter, E. Schögel and K. F. Hamann. Pfl
Arch. Ges. Physiol. 295(2):157-172, 1967.

Capacity of the main excretory duct of the ra
submaxillary gland to transform a plasma-like
primary saliva into a low Na, high K, final s
was studied using a technic of continuous mic
perfusion. When the duct was perfused with

SECRETION OF BILE IN RESPONSE TO FOOD WITH AND WITHOUT BILE IN THE INTESTINE.

Nahrwold, D. L. (VA Ctr., Los Angeles, f.) and M. I. Grossman. Gastroenterology):11-17, 1967.

enterohepatic circulation of bile was inter- ed in 3 cholecystectomized mongrel dogs by rnal diversion of bile through a catheter in common bile duct. This diversion caused a ed reduction in the rate of bile flow, a ease in bile salt conc. and an increase in rbonate conc. Feeding with the enterohepatic ulation interrupted produced secretin-like eresis with increased bicarbonate conc. and ut; however, it did not increase the bile conc. or output. When bile was infused into duodenum, no increase in the vol. rate of flow ile occurred; however, the bile salt conc. output increased. Simultaneous feeding infusion of bile into the duodenum produced eresis characterized by high bile salt and arbonate conc., with bile salt output greater with bile alone and bile bicarbonate output ater than with food alone. The reason for reased bile salt output when food and bile e admin. simultaneously is not clear; possibly, reased intestinal motility which occurs during ding resulted in more rapid transport of infused e to the distal intestine where absorption urs, the presence of chyme facilitates the orption of bile salts, or endogenous production bile salts is increased under these circum- nces.

8 PANETH-CELL FUNCTION. (E.) Creamer,

B. (St. Thomas Hosp., London). Lancet 485):314-316, 1967.

patients with Paneth cell deficiency the most minent findings were a diminution of crypt ivity and damage to the epithelium of the ll intestine. Anatomical and secretory studies Paneth cells are reviewed and a hypothesis of ir function is proposed. It is suggested t the Paneth cells secrete a complex of protein carbohydrate which forms a luminal environment cessary for rapidly dividing and maturing cells for the epithelium on the villi. This mechan- n ensures an almost constant conc. of amino ids in the intestinal lumen, during both fasting d feeding, irrespective of diet. Paneth cells n be looked upon as specialized units providing minal nutrition for crypt cells and endogenous otein for the small intestine. The occurrence Paneth cells in intestinal metaplasia of the stomach may explain the high mitotic rate in this condition. Distal colitis is not accompanied by carcinoma while total colitis frequently is, and Paneth cells are rare in the sigmoid colon and rectum in this condition. An absence of Paneth cells in the small intestine is accompanied by abnormal crypts and surface epithelium which could well be explained by a lack of luminal nourishment.

7849 EFFECT OF NUTRITIONAL PATTERNS UPON THE PANCREATIC SECRETORY ACTIVITY. (Rus.)

Fomina, L. S. (Nutrition Inst., Acad. Med. Sci., Moscow). Vop. Pitan. 25(5):27-32, 1966.

Dogs (3-4/series) were provided with pancreatic fistulae and divided into three groups according to the type of diet which they were fed, which was for 18-27 days (11-18 days for controls); Group 1, fed a diet consisting of 2% fats, 20% proteins and 78% carbohydrates, and whose matched controls were fed a diet consisting of 29% fats, 20% proteins and 51% carbohydrates; Group 2, fed a diet consisting of 60% fats, 20% proteins and 20% carbohydrates, and whose matched controls were fed a diet of 30% fats, 20% proteins and 50% carbohydrates; and Group 3, fed a diet consisting of 9.6% fats, 8.4% proteins and 81% carbohydrates, and whose matched controls were fed a diet consisting of 33% fats, 22% proteins and 45% carbohydrates. It was found that secretion of enzymes by the pancreas is related to the nature of animal nutrition. The greatest increase in pancreatic secretion was found in animals of Group 3 (av. for controls was 4.5 ml/hr. and for experimental animals, 27.5 ml/hr.). Amylase secretion was increased in experimental animals of Group 1; proteinase at first decreased, then reached initial values or exceeded the latter, and lipase secretion was increased. With experimental animals of Group 2, amylase conc. was decreased, lipase was increased to a variable degree and proteinase initially decreased and then increased. These shifts in enzyme secretion were considerably dependent upon the type of components in the diet, such as fats. For experimental animals of Group 3, amylase and proteinase secretion were decreased, while lipase secretion was increased, although its conc. in pancreatic juice was somewhat decreased. The lipase:amylase was increased in animals in Groups 2 and 3, and the lipase:proteinase ratio was increased in Group 3 animals.

7850 A STUDY OF THE SECRETORY ACTIVITY IN MITOTIC ACINAR CELLS OF THE PANCREAS.

(Rus.) Kazaniev, V. V. (Inst. Human Morphol., Moscow). Biull. Eksp. Biol. Med. 62(11):94-96, 1966.

The relationship between cellular division and function was studied in pancreatic acinar cells of albino mice. Male mice (5-6 g wt.) of Group 1 were fasted for 10-12 hr., and those of Group 2 received food 1 hr. before sacrifice, which occurred during the period of max. mitotic activity. During mitosis, cellular functional activity was not completely inhibited. The capacity of cells to form and secrete granules was also preserved during mitosis. Several other processes concerned with secretion during mitosis were weakened or even completely inhibited. A decrease in the number of prozymogenic granules in the basal portion of the mitotic cell indirectly revealed a decrease in the formation of secretory substance during mitosis. Thus, the hypothesis of antagonism between the work and division of the cell only unilaterally reflects the complicated relationship of these processes. Only some of the special functions are depressed during mitosis. The content of amino acids (tyrosine, tryptophan, histidine) in zymogenic granules was approx. the same in dividing and interphase cells. The intensity of excretion was independent of the phase of mitosis.

7851 SECRETION OF CALCIUM BY THE CANINE PANCREAS. (E.) Zimmerman, M. J. (Mt. Sinai Hosp., New York, N. Y.), D. A. Dreiling, I. R. Rosenberg and H. D. Janowitz. Gastroenterology 52(5):865-874, 1967.

In 19 experiments on fasting dogs with permanent Thomas duodenal cannulas, secretion was stimulated by a single i.v. inj. of secretin (5 U/kg); in 10 other experiments, pancreozymin (2 U/kg) was added to the same dose of secretin. In 3, the effect of constant infusion of varying doses of secretin was also studied. Basal pancreatic juice total Ca ranged from 3.3-4.4 mEq/liter, with corresponding serum Ca from 4.0-5.5 mEq/liter. Ca conc. varied inversely with rate of flow and bicarbonate conc. At peak flow rates, Ca conc. fell to extremely low levels but returned to resting levels within 30-40 min. An initial rise in Ca output paralled the "washout" of enzyme. When pancreozymin was added to secretin, Ca output was augmented beyond that which could be ascribed to the known contamination of pancreozymin by secretin. These results indicate that total Ca is not correlated with the major electrolyte (bicarbonate)-containing fluid, and may be related to the enzyme-containing fraction.

7852 ENHANCEMENT OF PANCREATIC ENZYME SYNTHESIS BY PANCREOZYMIN. (E.) Rothman, S. S. (Harvard Med. Sch., Boston, Mass.) and H. Wells. Amer. J. Physiol. 213(1):215-218, 1967.

Pancreozymin (20 U/kg), secretin (20 U/kg) or methacholine (5 mg/kg) were inj. s.c. 3 times/day for 4 days into Holtzman rats (both sexes); the rats were fasted and sacrificed 16 hr. after the last inj. Pancreozymin, but not secretin or methacholine, caused a significant increase in pancreatic wt. which was attributable to hypertrophy of pancreatic acinar cells. In the enlarged pancreas, tissue conc. of trypsinogen, chymotrpsinogen and amylase were significantly increased. The change in enzyme conc. was "nonparallel", since the increase in chymotrypsinogen and amylase was more marked than that of trypsinogen. These results indicate that pancr zymin enhances the synthesis of these 3 exporta pancreatic enzymes.

7853 CALCIUM CONTENT OF DUODENAL JUICE. (Hansky, J. (Monash U., Melbourne, Australia). Amer. J. Dig. Dis. 12(7):725-733, 1967.

Duodenal intubation and stimulation with secret (1 U/kg and 3 U/kg) were performed on 20 normal subjects and 18 patients with chronic pancreati 4 with cancer of the pancreas, 4 with alcoholic cirrhosis and 2 with hyperparathyroidism. Amyl bicarbonate and Ca content of the duodenal flui was determined. Basal fasting Ca conc. in norm subjects was 3.0 mg/100 ml; after inj. of 1 U/k of secretin the conc. was 2.3 mg/100 ml. Large doses of secretin produced a fall in Ca conc. t a low of 1.8 mg/100 ml with 3 U/kg of secretin, but the rate of secretion of Ca was independent of the secretin dose. Subjects with chronic pancreatitis and alcoholic cirrhosis had increa basal and postsecretin conc. of Ca in duodenal fluid, but the output of Ca was more variable. Two patients with hyperparathyroidism gave evidence of normal pancreatic function in respo to standard secretin tests, but showed increase Ca conc. in basal fasting juice. The implicati of these results are discussed in terms of pancreatic calcification and the association between pancreatitis and hyperparathyroidism.

7871 DISTRIBUTION OF THE ACTIVITY OF VARIOUS HYDROLASES, TRANSAMINASES, AND GLUTAMIC DEHYDROGENASE IN THE DIGESTIVE TRACTS OF FED AND FASTED RATS. (E.) Hsu, L. (U. California Sch. Med., San Francisco) and H. Tarver. Gastroenterology 53(1):78-87 1967.

Long-Evans and Sprague-Dawley rats were divided into fasted and nonfasted groups, and the distribution of various enzymes in their stomach, small intestine, cecum and colon was assessed. Cathepsins D and C were present in tissue homogenates prepared from all segments of the digestive tract of the rat. Some catheptic activity (as cathepsin D) was also found in the lumen of the stomach, but in the intestinal lumen such activity was small compared to that of trypsin and chymotrypsin. Glutamate dehydrogenase, aspartate aminotransferase, alanine aminotransferase and leucine aminopeptidase also were active in homogenates from all the segments of the tract, as well as in the luminal contents whether the rats were fed or fasted. Aryl sulfatase, β-glucuronidase and alkaline phosphatase activities were also present in both tissues and luminal contents. The proteases were present in the digestive tract of both fasted and fed rats, although in the fasting state there was an overall decrease in the proteolytic activity as well as in the conc. of protein and the products of its digestion. These findings indicate that the desquamated epithelial cells of the digestive tract mucosa contribute nonhydrolytic as well as hydrolytic enzymes to the lumen. Differential centrifugation of rat intestinal mucosa in sucrose indicated that the 2 cathepsins may be associated with lysozome-like particles. The activity of aspartate aminotransferase was found to sediment with that of glutamate dehydrogenase, whereas the intracellular distribution of alanine aminotransferase and alkaline phosphatase appeared to be less well-defined. Most of the leucine aminopeptidase activity was recovered in the cell supernatant fluid. The possible physiological significance of the enzymes acting on α-amino N in the lumen of the digestive tract is discussed. The gastrointestinal tract is also considered as a possible site for the breakdown of the plasma proteins, both intracellularly and extracellularly.

7872 THE CHEMISTRY AND PHYSIOLOGY OF SPECIFIC TRYPSIN INHIBITORS FROM THE PANCREAS OF CATTLE, DOG, HOG, AND MAN. (Ger.) Fritz, H. (U. Munich, Germany), I. Hüller, M. Wiedemann and E. Werle. Hoppe Seyler. Z. Physiol. Chem. 348(4):405-418, 1967.

Trypsinogen, trypsin, and trypsin inhibitor levels were assayed in the dog before and after i.m. inj. of 2.5 mg carbamylcholine; the secretions had parallel conc. of enzyme precursors and enzyme inhibitors. The specific inhibitors were then extracted from the pancreas of the hog, dog, cattle (ox) and man, and separated from trypsin by the formation of an insoluble trypsin-resin complex; the relatively low molecular wt. of t inhibitors made their separation easy; they we conc. by absorption on Sephadex columns. Each trypsin inhibitor, isolated from a different animal species, was further resolved by high voltage electrophoresis into 3 fractions, sti inhibitory, having the same amino acid composi as the specific inhibitor of the animal from which they were taken. Molecular wt. of the inhibitors (not the fractions), calculated fro the amino acid composition, were for dog 5636 (53 amino acids); hog 5695 (53 amino acids); cattle 5919 (54 amino acids) not including the amide groups. Each inhibitor from these 3 spe contained 2 tyrosine residues, but not tryptop histidine or phenylalanine. The 4 species-specific inhibitors did not inhibit α-chymotry kallikrein, plasmin, thrombin, or papain. The equilibrium between trypsin and the specific inhibitor was established very rapidly, after which the inhibition remained constant in the range 5.5-11. Human and hog trypsin inhibitor inhibited the enzyme stoichiometrically up to 100%; but a 50-60% excess of trypsin inhibitor of dog or cattle was required for complete inhibition. Bovine trypsin inhibitor acted no competitively, but the inhibitors of the other species behaved competitively toward trypsin i the presence of N-benzoyl-DL-arginine-p-nitroanilide. The 4 inhibitors showed the property of temporary inhibition against their own degr tion; when an inhibitor was present in an exce of trypsin at a pH of 7.8 and a temperature of 37° C, the inhibitor was degraded only very slowly; however, when the inhibitor was bound trypsin it was quickly degraded by free trypsi in the preparation. The parallel secretion of trypsinogen and trypsin inhibitor suggests the possibility that both may be stored in the sam zymogen granules to inhibit prematurely-activa trypsin in the glands or in the ducts.

7873 FILLING OF THE GALLBLADDER DURING DIGESTION. (ROENTGENOLOGIC INVESTIG TION). (Rus.) Antonova, G. M. (I. P. Pavlov Inst. Physiol., Leningrad, USSR). Fiziol. Zh. SSSR Sechenov 53(1):102-105, 1967.

This study was made on 7 randomly-bred dogs (3-7 yr. old; 11-18 kg body wt.) with or witho a gallbladder fistula; food stimulants include raw egg yolk (50 g), milk (600 g) and meat (10 g); cholecystography was made 5-180 min. after the admin. of biligraphin (0.2 ml/kg) which was used as contrast material. After a brief late period which followed feeding, motor activity of the gallbladder was increased and the secre of bile began. Entry of hepatic bile into the gallbladder was independent of the type of foo and it persisted during the entire process of digestion due to periodic changes of the sphinc tonus of the gallbladder duct and the terminal portion of the common bile duct. At the time c active gallbladder contraction, there were peri

cretion of bile into the intestine, which
delayed during stimulation of tonus in the
ncter of Oddi. In the latter case the move-
of bile was toward the gallbladder. The
w of contrast bile in the gallbladder was
intensive and smaller in the fed animals.
degree of gallbladder contraction was food-
ndent. Gallbladder bile entered the intestine
ox. every 30-40 min. after stimulation with
. Contrast bile filled the gallbladder 10-
in. after cholecystography following milk
ing; secretion of bile into the intestine
rred in the subsequent 15-20 min., and the
duration of bile secretion into the intestine
approx. 20 min. In various dogs after the feed-
of egg yolk, the periods of bile entering the
bladder, and its secretion into the intestine,
of similar duration; bladder filling usually
ed 19-25 min. and was followed by 15-20 min.
o filling. During the feeding of meat, milk
egg yolk to dogs with gallbladder fistulae,
entrance of liver bile into the gallbladder
rred during those brief and rare periods of
eased tonus of the gallbladder cervix. In
rast to healthy dogs, in operated dogs the
etion of contrast liver bile into the intestine
ample both in the presence and absence of
stion. Active gallbladder motility occurred
at the gallbladder cervix and the adjoining
s, while portions closer to the fistula re-
ed inactive. In open gallbladder fistulae,
did not completely evacuate the gallbladder
accumulated to a considerable amount in the
st regions of the gallbladder.

INFLUENCE EXERTED BY NITRITES AND
NITRATES UPON SOME DIGESTIVE ENZYMES.
.) Popov, V. I. (Cent. Inst. Postgrad. Med.,
ow). Vop. Pitan. 25(6):29-33, 1966.

effect of single or repeated doses (admin.
) of nitrites (NO_2, 2.7 mg/kg; as the K salt,
/kg) or nitrates (NO_3, 40.8 mg/kg; as the K
, 66.5 mg/kg), or a combination of both, on
activity of digestive enzymes was studied in
albino rats (210-250 g). A single admin.
O_2 had no effect. NO_2 and NO_3 one time
eased the activity of alkaline phosphatase
pprox. 54%, and that of enterokinase by approx.
while the activity of lipase was increased
pprox. 28%. The repeated admin. of NO_2
lted in a decrease of alkaline phosphatase
the tenth day of treatment, but it reached
same values as controls by the twentieth and
rtieth day of the experiment; enterokinase and
se activity was decreased by the tenth day
it reached control values by day 20 and again
reased by the thirtieth day. Under NO_2 and
treatment, the activity of lipase and alkaline
sphatase remained at control levels up to the
th day of the experiment, but by the twentieth
they were markedly decreased and remained so
to the thirtieth day of the experiment; the
ivity of enterokinase showed a decrease only
the thirtieth day of the experiment. There
a cumulative inhibitory effect upon pancreatic lipase and alkaline phosphatase when NO_2 and NO_3 were admin. simultaneously. Thus, NO_2 and NO_3 had an unfavorable effect upon the organism, and it would seem expedient to limit their use in food.

7875 THE IMPORTANCE OF GLUCOSIDIC ENZYMES DURING THE SPLITTING OF MALT-OLIGO-SACCHARIDES AND STARCH. (Ger.) Ruttloff, H. (Inst. Nutr., Potsdam-Rehbrucke, Germany), R. Friese and K. Täufel. Hoppe Seyler. Z. Physiol. Chem. 348(6):705-710, 1967.

Comparative studies on the glucosidic enzymes, homogenates of the mucosa and intestinal juices of the rat and pig, and α-amylase from the pancreas were undertaken using malt-oligosaccharides (maltose, maltatriose, maltatetrose, and maltapentose) and starch as substrates. α-Amylase was purified from the pancreas of rat and pig by standard methods; the glucoamylases were obtained by freeing them from homogenates by use of trypsin, centrifuging, and then conc. and isolating the enzymes by column chromatography. Enzyme activities were determined by measurement of liberated glucose. In order to obtain glucosidases free of α-amylase the preparations in soln. were heated to 50° C for 15 min., completely inactivating the α-amylase. α-Amylase produced glucose from the tri-, tetra-, and pentasaccharides but its glucosidic activity was too low to be significant; this was especially true in extracts of the mucosa. Taking the α-amylase activity (internal splitting of substrate molecule) of each source as equal to 100, the glucoamylases were equal to 3 in rat mucosa, 2.5 in pig mucosa and 0.5 in intestinal juices of rat and pig. In the intestinal lumen, maltatriose was hydrolyzed exclusively by glucosidic enzymes (chiefly glucoamylase). The tetra- and pentasaccharides were hydrolyzed both from the center (α-amylolytic) and terminally (glucosidic). The glucosidic activity was mainly of the glucoamylase type. The glucosidase activities measured in the intestinal juice consisted of about equal proportions of α-amylase and glucoamylase.

AN EXCITATORY ADRENERGIC ALPHA RECEPTOR
MECHANISM OF TERMINAL GUINEA-PIG ILEUM.
Reynolds, D. G. (Walter Reed Army Med.
, Washington, D. C.), G. E. Demaree and M. H.
fer. Proc. Soc. Exp. Biol. Med. 125(1):
3, 1967.

terminal ileum was removed from each of 10
ea pigs, and bathed in a balanced, buffered
rolyte soln. of the following composition:
laCl, 0.2 g KCl, 0.15 g $CaCl_2$, 0.05 g
O_4, 0.2 g $MgCl_2$ $6H_2O$, 1 g $NaHCO_3$ and 1 g
ose per liter. The following drugs were
as adrenergic test agents in differential
tor blockade sequences in order to
idate the adrenergic mechanism involved:
lephrine, epinephrine, norepinephrine and
renaline. The action of these agents was
ed on the tissue during its stimulation by
lcholine. Phenoxybenzamine was used as an
nd propranolol as a β-adrenergic receptor-
blocking agent. Alpha-receptor blockade
lted from a 30-min. exposure to 2.5 x 10^{-9}
oxybenzamine, while propranolol (4 x 10^{-6})
30 min. produced an effective, but not
lete, β block. Other drugs used included
amine, diphenhydramine, serotonin, reserpine,
pine and morphine. Phenylephrine caused a
raction of ileum which resembled a pure
ceptor site response. Both epinephrine and
inephrine produced biphasic responses which
owed a pattern of α excitation followed by β
bition, while isoprenaline elicited a pure β
bitory action. Use of phenoxybenzamine as an
ocking agent abolished all excitatory
onses while augmenting β- actions.
ranolol, through β-adrenergic receptor site
kade, potentiated α-excitatory actions. It
uggested, on the basis of these studies, that
terminal guinea-pig ileum possessed an
ue α-adrenergic receptor mechanism which is
tatory in nature.

ADDITIONAL EVIDENCE FOR THE PARTICIPATION
OF 5-HYDROXYTRYPTAMINE IN THE INTESTINAL
ONSE TO MORPHINE. (E.) Burks, T. F. (U.
Coll. Med., Iowa City) and J. P. Long.
. Soc. Exp. Biol. Med. 125(1):227-230, 1967.

tal of 2470 young adult male Swiss Webster
e mice were randomly divided into groups of
nimals each. Powdered charcoal was suspended
lycerine and admin. p.o. to the animals in
of 1 ml, and the animals were sacrificed 20
after receiving the charcoal meal. Morphine
doses of 1.2-5.0 mg/kg), physostigmine
mg/kg), serotonin (10 mg/kg) and saline
admin. to the animals 10 min. before
coal; methysergide (10 mg/kg) and atropine
mg/kg) were given 30 min. before charcoal;
reserpine (5.0 mg/kg) was given 16 hr. before
coal. The effects of these agents on
rointestinal propulsion of the charcoal meal
assayed. Morphine and 5-hydroxytryptamine inhibited intestinal propulsive activity. Delay of passage of a charcoal meal through the mouse small intestine by morphine was antagonized by methysergide, a potent inhibitor of 5-hydroxytryptamine. Treatment with reserpine failed to modify the intestinal response to morphine. The effects of atropine on morphine and 5-hydroxytryptamine were similar; treatment with atropine enhanced the delay in intestinal transit produced by these agents. Treatment with physostigmine failed to alter the intestinal effects of either serotonin or morphine. These results were interpreted as supporting the hypothesis that some of the actions of morphine on the mammalian small intestine may be mediated by serotonin.

7883 PLASMA VILLIKININ. (E.) Johnston, C. L., Jr. (Med. Coll. Virginia, Richmond), E. Kokas and E. S. Barrow. Proc. Soc. Exp. Biol. Med. 125(1):281-284, 1967.

Outdated human plasma was processed in 200 ml batches, and crude extracts were harvested by processes used to obtain intestinal mucosal and urine extracts of villikinin. Each sample was tested for its effect upon villous motility. It was found that plasma contained a material capable of markedly increasing villous motility. It was not possible to distinguish a difference between the activities of crude mucosal, plasma and urine preparations of villikinin, although it is suggested that there may be conc. differences. Refined preparations of villikinin showed a similarity to mucosal and urine extracts in activity as well as mobility, but it was not possible to demonstrate antivillikinin in preparations other than those from intestinal mucosa. Extracts from bovine and canine plasma gave identical results to those obtained with extracts from human plasma. The activity of villikinin was different from that produced by histamine, serotonin and bradykinin. It is concluded that these results clearly demonstrate the presence of villikinin in the plasma, and that plasma villikinin is similar to mucosal and urovillikinin.

7884 FUNDAMENTAL RESEARCH FOR THE PHARMACOLOGICAL ACTIVITY OF ORIENTAL DRUGS. IV. ON THE SYNERGISM FOR THE ACTION OF CHOLEKINESIS BETWEEN COMPONENTS CONTAINED WITHIN THE CRUDE DRUG "BEZOAR ORIENTALE". (STUDIES ON THE FUNCTION OF SMOOTH MUSCLES. II.). (Jap.) Kimura, M. (U. Toyama, Japan), E. Osada, S. Kagami and D. Shiho. Yakugaku Zasshi (J. Pharm. Soc. Jap.) 87(5):550-553, 1967.

The cholagogic action of the crude drug, oriental bezoar, was examined by dividing its action into contraction of the gallbladder and relaxation of the sphincter of Oddi in the pig. It was found that, among the components of bezoar, the substance which causes contraction of the smooth muscle (a peptide-like substance) was the only one which caused contraction of the gallbladder and of the sphincter of Oddi; most of the other bile acid salts had a relaxing effect. Deoxycholate had the strongest relaxing action on the sphincter of Oddi and this was found to be the principle which caused cholagogic action by the bezoar. The smooth muscle-contracting substance inhibited the relaxing action of deoxycholate in the gallbladder. It is concluded that pharmacologically antagonistic substances, acting on the same point, formed a functionally co-operating system which effected cholagogic activity.

7885 THE SERIES ELASTICITY OF ACTIVE TAENIA COLI IN VITRO. (E.) Åberg, A. K. G. (U. Goteborg, Sweden). Acta Physiol. Scand. 69(4):348-354, 1967.

The series elastic components of smooth muscle taenia coli of the guinea pig were studied. The rate of isotonic shortening after release of an isometrically contracting taenia coli showed that the muscle behaved like a model with contractile elements in series with elastic components. Thus, taenia coli has series elastic components in the same sense as it has been described for striated muscles and heart muscles. At 37°C and full isometric tension, the series elastic components in taenia coli in vitro were measured to be extended, on the av., 13.1±2.7% of L_0 (the greatest length of an inactive muscle when the force applied to straighten it did not exceed 50 dynes). Max. "isometric" work developed during an isometric contraction was approx. 30% of the max. work that the muscle could perform during an isotonic shortening.

7886 PARADOXICAL INTESTINAL INHIBITORY EFFECTS OF STAPHYLOCOCCAL ENTEROTOXIN. (E.) Shemano, I. (Nat. Drug. Co., Philadelphia, Pa.), J. T. Hitchens and J. M. Beiler. Gastroenterology 53(1):71-77, 1967.

Highly purified staphylococcal enterotoxin (100 μg/kg, admin. i.v.; obtained from a strain S-6(Staphylococcus aureus) induced emesis, diarrhea and a marked depression of intestinal tone and contractility in conscious trained dogs with Thiry-Vella loops, Mann loops or cecostomies. The enterotoxin markedly inhibited intestinal transport in dogs, as shown by charcoal meal, sponge bolus studies, and X-ray studies using a Ba meal. Gastric emptying time was also markedly delayed. In contrast to these findings in conscious dogs, no intestinal inhibition was seen in dogs anesthetized with pentobarbital. Neither chronic bilateral vagotomy nor chemical sympathectomy (guanethidine and N,N-diisopropyl-N'-isoamyl-N'-diethylaminoethylurea) markedly influenced the intestinal depressant effects of enterotoxin. Enterotoxin exerted no effects on spontaneous contractility or tone of isolated rabbit ileum in bath conc. up to 10 μg/ml, nor did it influence the spasmogenic effects of acetylcholine or $BaCl_2$. These findings indicate that enterotoxin-induced diarrhea in these experiments cannot be explained by increased intestinal motility and transport. It is possible that the observed diarrhea is attributable in part to alterations in fluid flux into and out of the intestinal lumen. The mechanism of the intestinal depressant effec of enterotoxin must still be elucidated; it does not seem to be related to a direct action on intestine, an atropine or papaverine-like effect central vagal inhibition, a peripheral release of catecholamines, or enterotoxin-induced nausea and vomiting.

7887 RELEASE OF INTESTINAL 5-HYDROXYTRYPTAMI BY MORPHINE AND RELATED AGENTS. (E.) Burks, T. F. (U. Iowa, Iowa City) and J. P. Long J. Pharmacol. Exp. Ther. 156(2):267-276, 1967.

The release of serotonin into the perfused vasculature of isolated dog intestinal segments occurred after intra-arterial admin. of morphine meperidine, methadone, levorphanol, nalorphine, apomorphine or codeine. The duration of seroton release corresponded approx. with the increased intestinal tone which was produced. Codeine and morphine were less potent spasmogens of the dog intestine during periods of serotonin tachyphylaxis than during control periods. Perfusion of the isolated dog intestinal segment with Ca ion-deficient soln. reversibly decreased intestinal responses to acetylcholine, nicotine, serotonin, levorphanol, codeine and morphine. K-deficiency had no significant effects. The in situ intestinal responses to morphine were decreased in reserpine-pretreated dogs. It is suggested that serotonin participates in responses of the dog intestine to morphine and related agents.

7888 INHIBITION OF INTESTINAL MOTILITY IN MAN BY GLUCAGON GIVEN INTRAPORTALLY. (E.) Kock, N. G. (U. Goteborg, Sweden), N. Darle and G. Dotevall. Gastroenterology 53(1): 88-92, 1967.

The effect on intestinal motility of intraportal inj. of glucagon was studied in 7 patients (5 of whom had cholecystectomy due to gallbladder stones, 1 had intestinal resection due to stenosing regional enteritis and 1 had a transverse colostomy due to an inoperable sigmoid cancer). Glucagon was inj. by plastic tube that had been introduced into an omental vein at operation 5-7 days previously; that glucagon actually reached the portal vein was verified by inj. radiopaque medium and also by counting radio-activity over the liver after inj. of radioactive Xenon into the omental vein. The effect of glucagon on intestinal motility was recorded by a balloon method. Intraportal inj. of 0.05-0.1 mg glucago inhibited motility in both the jejunum and colon the inhibitory effect appeared within 30-60 sec. after inj. After intraportal inj. of 0.1 mg glucagon, the inhibitory effect lasted approx. 8 min., and after inj. of 0.05 mg the effect

ed 4-5 min. Inj. of glucagon into a brachial
in the same doses produced similar intes-
l inhibition in patients studied before and
r operation. The latency was 30-60 sec., and
duration of inhibition was as long as when
drug was given intraportally. Placebo inj.
ml of 0.9% NaCl soln. into the omemntal vein
nto the brachial vein did not induce any
bition. The effect of i.v. inj. of glucagon
the same in subjects who had not undergone
ery. Since glucagon inhibited intestinal
lity similarly after both routes of admin.,
inhibitory effect of glucagon was not
ted on passing through the liver. Since the
shold dose of glucagon was identical for
routes of admin., either all of the inj.
agon passed the liver unchanged, inducing
stinal inhibition on reaching the intestine
he systemic circulation, or the glucagon was
erted by the liver to some other substance
h still had the same pharmacological effect
ntestinal smooth muscle as glucagon.
rnatively, the glucagon in the liver may have
rated some substance with the same inhibitory
erties as glucagon.

ACTIONS OF CALCIUM AND CERTAIN MULTI-
VALENT CATIONS ON POTASSIUM CONTRACTURE
UINEA-PIG'S TAENIA COLI. (E.) Imai, S.
yo Med. and Dent. U., Bunkyo-ku, Tokyo) and
akeda. *J. Physiol. (London)* 190(1):155-169,
.

uffers and multivalent cations were used to
rmine the effect of severe Ca deficit on
K contracture (spike phase) of guinea pig
ia coli, and to determine the source of the
Lack of Ca led to the extinction of the
ial phasic response (which was preferentially
cted) of the pig's taenia coli at conc.
w 10^{-7} M. At conc. of 10^{-8} M the tonic
onse persisted, although diminished. Various
ivalent cations augmented the remaining tonic
onse but did not restore the phasic response
a-free media. These cations, when K
ractures were induced in normal Ca media,
ished the phasic response and partially
essed the tonic phase, and inhibited some of
fully developed contracture. It was concluded
the phasic response and some of the tonic
onse depend upon extracellular Ca for
iating them, and for maintaining tension in
of the tonic response. Bound Ca is involved
he remainder of the tonic response, and is
ased by sustained membrane depolarization.

THE "GLASS BALL TEST", A METHOD FOR
TESTING THE EFFECT OF DRUGS ON THE
NIC PERISTALSIS OF THE RAT. (Ger.) Schottek,
Martin Luther U., Halle-Wittenberg, Germany).
eimittelforschung 17(5):649-650, 1967.

effect of drugs upon the peristalsis of the
e intestine can be assayed in the rat *in vivo*
ugh the glass ball test. The rate of transportation of a glass ball 6 mm in diameter through 6 cm of large intestine is measured in the nonoperated, nonnarcotized animal. The glass ball is inserted into the ampulla recti and then carefully pushed into the large intestine by means of a glass rod which is easily done with only slight pressure. Using rats (200 g) and inserting the glass ball for no more than 6 cm no difficulty is encountered. Under normal conditions in 88 trials, the time for the ball to travel 6 cm was 16± 5.4 min. or about 0.4 cm/min. The inhibition of large intestinal peristalsis to a passage time of 1 hr. or more is considered clear evidence of inhibition of the colon; this has been observed with morphine, methadone, codeine and pethidine. The test can be equally well applied to the evaluation of drugs which stimulate peristalsis, when the time of passage may be only 3-4 min. The guinea pig offered a passive resistance to the insertion of a glass ball into the ampulla recti. The stretching of the lower large intestine also seemed unduly severe. However, the test does work in mice where the diameter of the glass ball should be 3 mm and the total distance of insertion should be 2 cm. The time of passage is about 6 min. or about 0.3 cm/min.

7891 INTESTINAL MOTILITY IN MAN: THE EFFECT OF BRADYKININ ON THE MOTILITY OF THE DISTAL COLON. (E.) Murrell, T. G. C. (U. Adelaide, S. Australia) and D. J. Deller. *Amer. J. Dig. Dis.* 12(6):568-576, 1967.

The effect of bradykinin on intestinal motility was studied in 43 subjects (25 men, 18 women); the motility indices of 14 with normal intestinal function were compared with those of 14 patients with diarrhea and 15 with constipation; of the 29 with disturbed intestinal function, 14 had the irritable-colon syndrome. Patients with active diarrhea due to gluten-sensitive enteropathy (4), ulcerative colitis (3), and pancreatic and postgastrectomy steatorrhea (4), and patients with constipation due to carcinoma of the rectum (2) and diverticulosis (2) were included. Three open-ended catheters of 1.5 mm diameter were inserted through a sigmoidoscope to approx. levels of 25, 18 and 11 cm from the anus, and the resting pattern of motility was first recorded for 30 min. After an i.v. inj. of isotonic saline, 0.1 mg of bradykinin in 20 ml of isotonic saline was admin. i.v. at a rate of 10 μg/min. for 3-5 min.; the rate was increased to 20 μg/min. for the remaining amount of 50 μg, if this dose could be tolerated by the subject. A full single dose of 100 μg was used in all but 7 of 43 subjects. The effect of a second infusion of bradykinin was examined in 3 subjects with the irritable-colon syndrome in whom motility had been augmented by 1 mg of prostigmine inj. i.m. 20 min. earlier. Bradykinin produced a decrease in motor activity in the distal colon in most controls as well as in patients with diarrhea and constipation; amplitude and duration of waves were equally reduced. However, response to bradykinin was not uniform and in controls a rise in motor activity to 200% or more was noted in 2 subjects. In all 43 subjects, bradykinin produced a decrease to 50% or less of the resting value of percentage activity in 27 subjects (62.8%), of whom 9 were controls, 9 had diarrhea and 9 had constipation. In 14 subjects (32.6%) there was no change in activity. In spite of variability of response, bradykinin generally produced a reduction in wave patterns which was most obvious in patients with diarrhea; of the 14 subjects in this group, bradykinin completely abolished motility in 6 and reduced the motility index below 50% of the resting level in another 3, while there was no change in 5. Variable response to bradykinin was also apparent in patients with the irritable-colon syndrome. The motor activity induced by prostigmine was abolished by bradykinin.

7892 ANAL SPHINCTER PRESSURE CHARACTERISTICS. (E.) Katz, L. A. (Yale U. Sch. Med., New Haven, Conn.), H. J. Kaufmann and H. M. Spiro. Gastroenterology 52(3):513-518, 1967.

A simple method for recording pressures in the anal sphincter during distention at rest and during voluntary contraction is presented. The resting sphincter resisted distention until a resting yield pressure was reached, after which further distention of the sphincter produced no further pressure rise. Max. sphincter pressure was reached by voluntary contraction only after the recording balloon had been distended to the vol. needed to reach the resting yield pressure. The ability of the sphincter to resist distention appeared to be the mechanism for maintaining continence at rest; however, contraction of the voluntary component of the anal sphincter can forcibly close the sphincter when distended and thereby maintain continence. Of 48 subjects studied, all 14 with incontinence were found to have normal resting yield pressures, but max. sphincter pressures varied depending upon the cause of incontinence. Most patients with incontinence had low max. sphincter pressure, but incontinence was not invariable with low max. sphincter pressure. It is possible to differentiate patients with incontinence as the result of abnormalities of the voluntary component of the anal sphincter from those patients with incontinence of other cause.

7893 IN VIVO CONTRACTILITY OF SMOOTH MUSCLE BY CHOLECYSTOKININ CONCENTRATES. (E.) Denton, R. W. (U. Illinois Coll. Med., Chicago) and L. L. Gershbein. Arch. Int. Pharmacodyn. 166(2):473-485, 1967.

A balloon and tambour apparatus was used for measuring the contractions of the stomach, gallbladder, small intestine and colon, in intact and vagotomized, anesthetized dogs prepared with gastrostomies, Pavlov and Heidenhain pouches, jejunostomies and cholecystostomies. Cholecystokinin concentrates (20-200 U) elicited contraction of the intact stomach, gallbladder, intestine and colon in dogs anesthetized mainly with pentobarbital. The data collected were essentially in agreement with those collected earlier in vitro in guinea pigs. The stomach of the anesthetized dog underwent relaxation or showed no response to cholecystokinin concentrates, however, the awake vagotomized dog showed stoma contractions similar to those of the anesthetiz dog. Both anesthetized and nonanesthetized dog showed contractility of the intact gallbladder and intestine following cholecystokinin concentrates. As was previously described in in vitr studies, pituitrin antagonized the response of the dog gallbladder induced by cholecystokinin concentrates.

7894 THE ROLE OF GASTRIN IN GASTROILEOCOLIC RESPONSES. (E.) Connell, A. M. (Roy. Victoria Hosp., Belfast, Northern Ireland) and C. J. H. Logan. Amer. J. Dig. Dis. 12(3): 277-284, 1967

Intraluminal pressures were recorded from the small intestine using a pressure-sensitive radiotelemetering capsule and from the large intestine using miniature balloons. Normal volunteers (18) were used for the studies. Two preparations were studied: pure Gastrin II prepared according to the method of Gregory and Tracy, and the gastrin-like pentapeptide, ICI 50,123. ICI 50,123 was also studied in 2 dogs prepared with Thiry fistulas. No consistent effect on the terminal ileum was found with Gastrin II (0.25 μg/kg/min. for 3 min.). ICI 5 given both i.v., 0.25-0.5 μg/kg, and s.c., 2-4 μg/kg produced only small effects on the termin ileum. Rectal motility was increased by both Gastrin II and ICI 50,123 by the i.v. route. Comparable data was not available for Gastrin I but ICI 50,123 increased motility of the sigmoi rectosigmoid, as well as the rectum. In the do studies, atropine 0.3-0.6 mg depressed or abolished gastrin-induced motility. It is concluded that since the doses studied were at essentially physiological levels it is reasonab to postulate that gastrin released by eating stimulates colonic motility in man. The effect on the intestine were not clear and additional study is needed.

7895 GASTROINTESTINAL ACTIONS OF METOCLOPRA AN EXPERIMENTAL STUDY. (E.) Jacoby, H. I. (Merck Inst. Ther. Res., West Point, Pa.) and D. A. Brodie. Gastroenterology 52(4): 676-684, 1967.

In rats, metoclopramide [N-(diethylaminoethyl)-2-methoxy-4-amino-5-chlorobenzamide], at 16 and 32, but not at 8 mg/kg s.c., produced a significant acceleration of gastric emptying. Metoclopramide (2 mg/kg i.m.) caused a significant reduction (always 50% or more) in emptying time in 3 monkeys. Metoclopramide (1,2, and 4 mg/kg

) stimulated gastric contractile activity in
sthetized and unanesthetized dogs. No
nificant increase in gastric acid secretion
ld be observed in either rats or dogs, despite
marked stimulation of gastric motor activity.
tric motor stimulation was antagonized by
icholinergics (atropine 0.01 mg/kg i.v.) and
phine (0.4 mg/kg i.v.) but was not blocked by
ateral cervical vagotomy or by a ganglionic-
cking drug (chlorisondamine 1 mg/kg i.v.) plus
otomy. The action of metoclopramide appears
involve activation of intramural cholinergic
rons responsible for modifying gastric
ility but not acid secretion, either by a
ect stimulation or by removal of inhibitory
luences. Direct evidence for either mode of
ion was not obtained.

5 RADIOLOGIC STUDY OF ENDOCRINE CONTROL OF
GASTROINTESTINAL MOTILITY IN THE ALBINO
. I. EFFECT OF AN ASSOCIATION OF 17-ALPHA-
INYL-17-HYDROXY-5(10)-ESTRENE-3-ONE AND
INYLESTRADIOL-3-METHYL ETHER. (It.) Livrea,
(U. Messina, Italy), G. Longo and C.
rgianni. Boll. Soc. Ital. Biol. Sper. 42(24):
3-2056, 1966.

idely-used contraceptive mixture consisting of
parts ethinylestradiol-3-methyl ether plus
5 parts 17-α-ethinyl-17-hydroxy-5(10)-estrene-
ne was admin. daily to 4 male and 4 female, 90
-old, WAG rats by gastric sound (1.5 mg/10g/dose,
pended in 0.5 ml physiologic saline).
er 10 days of treatment, the stomach appeared
be somewhat increased in vol. and the duodenum
ld not be visualized. The stomach required
hr. to empty, as contrasted to slightly more
n 1 hr. in the same animals, prior to treat-
t. At the same time, the motility of the
ll intestine was somewhat increased, as com-
ed to pretreatment studies, and the colon
tinued to empty normally. Substantially
ntical effects were in evidence after 15 days
treatment. It is concluded that the mixture
rted a selective effect on the smooth muscle
the stomach, reducing motility appreciably,
le stimulating the motility of the small
estine to a slight degree and exerting no
cernible effect on the colon.

7 EFFECTS OF TETRODOTOXIN ON INNERVATED
SMOOTH MUSCLE PREPARATIONS. (E.)
shon, M. D. (U. Oxford, England). Brit. J.
rmacol. 29(3):259-279, 1967.

en muscle preparations were obtained from
mals: guinea-pig stomach (with thoracic vagi
celiac axis), cannulated through pylorus;
se stomach (similar to above) cannulated through
denum; longitudinal muscle of 3-cm length of
bit ileum; lengths of nonterminal guinea-pig
um (either as entire intestine or only
gitudinal muscle); fundus of rat stomach; rat
denum; guinea-pig taenia coli. The first 4
e stimulated electrically, the last 3 used to test drug response. Tetrodotoxin abolished effects produced by nervous stimulation. They recovered after removal of this agent. It abolished action potentials in the vagus nerve. All of its effects could be explained by block of nervous activity. In its presence, no response to any drug, except acetylcholine, was modified by either eserine or hyoscine. It was concluded that, in its presence, responses to drugs must have been direct effects on smooth muscle and not due in part to the release of acetylcholine. Tetrodotoxin abolished responses to drugs (nicotine, dimethylphenylpiperazinium iodide, choline phenyl ether, serotonin) which act only through stimulation of nerves; reduced responses to drugs which act partly by direct excitatory action on the muscle; potentiated responses to drugs, such as acetylcholine, whose actions were antagonistic to the direct excitatory muscle action; had no effect on responses to drugs whose sole action was on the smooth muscle. When the antagonistic neural response was dominant, as with choline phenyl ether, the muscle response was masked with tetrodotoxin. Response of guinea-pig ileum to drugs in the presence of this agent were the same as those of denervated longitudinal smooth muscle strips. It is concluded that the action of tetrodotoxin is limited to nervous tissue in innervated smooth muscle preparations.

7898 A METHOD OF MEASURING THE RATE OF PERISTALTIC MOVEMENTS OF THE GUT. (E.) Lockett, C. J. (U. Cape Town, South Africa). Lab. Pract. 15(12):1394, 1966.

The last few inches were removed from a Ryle tube, and a small rounded plastic tip inserted to seal it. Six glass relays were inserted in the tube, wired in series with thin resistance wire (10 ohms between relays), connected to an external battery, calibrating circuit, and Servo type pen recorder. In humans and dogs the tube was passed through the nose down the trachea into the stomach and duodenum, monitored by X-ray, and then connected to control box and recorder. A plastic-enclosed magnet was swallowed with a glass of water. When the apparatus is on, as the magnet passes each section of the tube, the relay closes and produces a signal rise equal to the value of the resistance between relay and battery, recording peristaltic rate and movement. Signals are recorded in step formation on squared graph paper and each section of the tube is identifiable (from the corresponding relay). A recent modification with micro-circuitry permits complete assemblage outside of the tube. The whole prewired apparatus is then inserted into the Ryle tube and both ends are sealed.

7899 STUDIES ON THE NORMAL DEGLUTITION COMPLEX. (E.) Vantrappen, G. (St. Raphael U. Hosp., Louvain, Belgium) and J. Hellemans. Amer. J. Dig. Dis. 12(3):255-266, 1967.

The deglutition complex was studied in 25 normal subjects. Intraesophageal pressures were measured with a set of 3 water-filled, open-tip catheters tied together with their distal ends 5 cm apart. The catheters were passed by mouth into the stomach. A "pull-through" technic was followed with measurements of resting and deglutitive pressures at 2-cm intervals. The initial negative deflection was observed in one-third the swallowing complexes occurring equally in the upper, middle, and lower esophagus. The mean speed of progression av. 50 cm/sec. The second positive wave was observed in 31% of complexes in the lower third of the esophagus, 14% in the middle third and not at all in the upper third. The terminal positive wave was found in 86% of deglutitions recorded, 80% were peristaltic, 20% were simultaneous. The origin of the initial negative deflection was studied by simultaneous intraesophageal and intrapleural pressure measurements. It was found that respiratory motions attend swallowing. The initial deflection in the swallowing complex appeared related to the initial dip in intrapleural pressure, which was considered to suggest that "swallowing respiration" may be responsible for the first component of the complex. The frequency of the second positive wave was increased by inserting a large tube into the stomach through the gastroesophageal sphincter; shunting resistance of the tube (by perforations) above and below the sphincter dropped the frequency to normal levels. The second positive wave was associated with peristaltic terminal peaks. It is concluded this wave is a passive phenomenon resulting from compression of the closed esophageal compartment ahead of peristaltic contractions.

7900 NEW METHODS OF STUDYING INTESTINAL TRANSIT TIMES. (E.) Rosswick, R. P. (St. George's Hosp., London), R. D. Stedeford and B. N. Brooke. Gut 8(2):195-196, 1967.

A simple, accurate, safe and economical method is described for determining intestinal transit time, using an araldite capsule of approx. 1 cm diameter, which has ^{131}I sealed in it (i.e., it is a pure gamma emitter yielding an activity up to 10 μc), and also some tiny Pb pellets. The capsule can be manufactured in the physics department of the hospital. A portable NaI scintillation counter, brought to bedside, determines capsule location to within 1 cm after screening the NaI crystal with a Pb collimator head. A transparent plastic table is placed over the patient's abdomen, and the movement of the ingested capsule is plotted on a grid marked on the table. Readings at 10-min. intervals are plotted on graph paper. Radiographic confirmation was done for this study, but is not thought to be necessary once the counting technic is practiced. The patient is not very inconvenienced, and may eat, drink, and go to the lavatory during the examination. Twenty-five determinations were done on 24 patients with Crohn's disease and with ulcerative colitis, and with patients with no known gastrointestinal disorder. It wa found that emptying of the stomach in ulcerativ colitis may be delayed, thus suggesting use of this method of transit time in differentiating between Crohn's disease and ulcerative colitis.

7901 A SIMPLE INSTRUMENT FOR THE MEASUREMEN OF INTESTINAL MOTILITY WITH IMPLANTED INDUCTION COILS. (Ger.) Engelhardt, W. (Vet. Inst., Hanover, Germany), G. Tolkmitt, H. J. Ehrlein and L. H. Stahlgren. Pflueger Arch. Ge Physiol. 294(3):229-234, 1967.

Long-term measurements (over periods of days or wk.) of intestinal motility have been done with a combination of strain gauges and induction coils, although strain gauges quickly lose sensitivity. A system employing only induction coils gave uniform responses for periods in excess of 3 wk. Construction of the coils was as follows: The ferrite core was 2.1 mm in diameter wound with 200 turns of Cu wire 0.08 m in diameter; diameter of the finished coil without housing was 5.0 mm, 2.5 mm high; housing wa thin plastic; leads were in a silicone tube. Induction between an implanted coil (secondary) and an overlying primary coil supplied by a transistorized 15 kilohertz oscillator was a function of the distance between the coils, the strength of the magnetic fields, and the number of turns in the secondary winding. As the coil must be small for many purposes and the distanc between them 1-5 cm, induced voltage was small; the output from the secondary was fed into a 3-stage transistorized amplifier with an oscilloscope output as well as a recorder outpu Calibration was simplified by potentiometric control of the oscillator output voltage. A schematic diagram is furnished in the paper. With this apparatus a number of factors in intestinal mobility have been investigated in 1 dogs for periods up to 3 wk.

7902 CONTRACTILE AND ELECTRIC ACTIVITY OF THE EXTRAHEPATIC BILIARY TRACT AND DUODENUM. (E.) Ludwick, J. R. (U. Michigan Med. Ctr., Ann Arbor) and P. Bass. Surg. Gynec Obstet. 124(3):536-546, 1967.

Contractile and electrical activities of the extrahepatic biliary tree and duodenum were monitored in dogs and monkeys which had been previously prepared with extraluminal strain gauge transducers and extracellular electrodes. No contractile or electrical activity could be detected from the common bile duct of the dog; in the monkey occasional spike potentials and low amplitude contractions occurred. No activi was recorded from the resting gallbladder in either species. Monkey duodenum did not show basic electrical rhythm as in the dog. Contraction of the intact bile duct (monkey) i response to epinephrine and 4-(m-chlorophenylcarbamyloxy)-2-butynyltrimethyl ammonium

ride suggests that the adrenergic system has
le in the activity of the common bile duct.
ecystokinin, methacholine, and morphine did
affect the bile duct. The gallbladder showed
ractile activity during the digestive period.
ecystokinin and methacholine induced con-
tions, epinephrine, 4-(m-chorophenyl-
amyloxy)-2-butynyltrimethyl ammonium chloride,
droxytryptophan and morphine did not. Chole-
okinin stimulated the duodenum to contract in
dogs and monkeys.

MODIFICATION OF THE CONTRACTILITY OF THE SPHINCTER OF ODDI BY CENTRAL ANALGESICS.
.) Juvara, I. (Cantacuzino Hosp., Bucharest)
D. Radulesco. Rev. Int. Hepat. 17(1):55-63,
7.

ee analgesics, frequently employed in the
ical and surgical treatment of biliary dis-
ers, cause strong contraction of the sphincter
ddi at the outset of therapy. These drugs
(1) dihydromorphinone-HCl, (2) pethidine and
a derivative of the group of heptanones (6-
thylamino-4,4-diphenyl-3-heptanone hydrochlor-
known as methadone HCl. The doses of these
ounds which are most active on the sphincter of
are identical with those employed for
gesia. To reduce the constriction of the
ncter, the spasmolytic activities of amyl
ite, atropine, chlorpromazine, and procaine
studied when admin. in the presence of the
gesics. The tests were made on 20 patients
biliary drains following cholecystectomy
mpanied with an exploration of the main bile
, but no operative sequellae or disease in
region. The intraductal pressure was
rded by a transducer, the variations of
age amplified and recorded as pressure changes,
le the bile duct was perfused at the constant
e of 1.5 ml/min.; external diameters of the
ducts exceeded 4 mm. The admin. of the
tral analgesics produced a strong increase of
sure in the main bile duct. Dihydromorphinone
ng i.v.) caused a pressure rise of 17 cm H_2O
2 min. Inhalation of 3 minims of amyl
rite abruptly and completely reduced the
ess pressure; the effect lasted only 5-6 min.
could be repeated during the period of
dual relaxation of the sphincter. On the
er hand, atropine (0.5 or 1 mg i.v.) had no
ion upon the contraction of the sphincter.
caine (20 ml 0.75% i.v.) had a variable
ect in some cases, not changing the pressure
others, causing a slow decline which did not
urn to the base pressure in the 45-min.
erimental period. Pethidine (50 mg i.v.) had
same pressure and time relationships with
pect to amyl nitrite and atropine. Chlor-
mazine was ineffective. Methadone (10 mg i.v.)
duced the greatest rise in the intraductal
ssure (about 18 cm H_2O); this was not reduced
atropine; amyl nitrite caused only a slight
transitory drop in pressure.

7904 COMPARISON BETWEEN SHAM FEEDING MEAT AND TEASING WITH MEAT ON CANINE GASTRIC MOTILITY.

(E.) Schapiro, H. (U. Tennessee Med. Units, Memphis), L. G. Britt and S. R. Evans. Amer. Surg. 33(6):499-500, 1967.

Three dogs were prepared with esophagostomies and gastric cannulae, and 3 dogs were prepared only with gastric cannulae. After a 15-20 min. control period, the animals were sham fed meat or teased with meat for a 5-10 min. period. In 5 studies on 3 dogs, the effect of sham feeding meat was an immediate and striking inhibition of gastric motility which lasted over 40 min. Nine experiments were performed on 6 dogs (3 of which had been used for sham feeding studies) to ascertain the effect of teasing with meat; in none of these was the gastric activity altered in any way during or for 30 min. after teasing with meat. This lack of response occurred during the period that the animals were secreting acid gastric juice. These results seem to indicate that a dissociation can exist between gastric secretion and gastric motor activity, and that, in all probability, different vagal centers exist to control these gastric functions.

7905 EFFECT OF MECHANORECEPTOR STIMULATIONS OF DIFFERENT INTENSITIES ORIGINATING FROM THE STOMACH AND LUNGS ON THE AFFERENT IMPULSATION OF THE CERVICAL VAGUS.

(E.) Varbanova, A. (Inst. Physiol., Bulgarian Acad. Sci., Sofia) and V. Sokolov. Acta Physiol. Acad. Sci. Hung. 31(2):107-113, 1967.

Acute experiments were done on immobilized artificallly-respired cats. Afferent vagal activity was led off by silver electrodes placed on the distal end of the vagus in the cervical region. The stomach was stimulated by 10-min. and 10-sec. distentions of a balloon introduced through the esophagus. The lungs were stimulated by the introduction of additional air into the system of respiration. At the beginning of stimulation vagal impulses were inhibited for a definite period, the duration of which was directly proportional to the intensity of stimulation (5-20 mm Hg). Upon stimulation, the vagal impulses gradually increased in amplitude reaching their highest values after the highest pressures over some tens of min. After reaching this max., the impulses gradually returned to the initial level. Compared with the period preceding stimulation, tonic vagal impulsation showed an increase in frequency which did not change during the entire period of stimulation, despite an increase in amplitude. Following stimulation, phasic vagal impulses gradually decreased in frequency parallel with the increase in amplitude.

7906 ELECTRICAL AND MECHANICAL ACTIVITIES IN THE STOMACH OF THE DOG: EFFECTS OF THE VAGUS NERVE STIMULATION, ATROPINE, NEOSTIGMINE AND ADRENALINE.

(E.) Sakamoto, S.

(Kumamoto U. Med. Sch., Japan) and K. Nishi. Kumamoto Med. J. 20(1):25-38, 1967.

Thirty adult dogs, starved for 24 hr., were anesthetized by i.v. inj. of amobarbital (50 mg/kg) and the abdominal cavity was widely opened by midline incision to expose the entire stomach. Suction Ag-AgCl electrodes were placed on serosal side of the pylorus and antrum, with the reference electrode fixed in the center of the abdominal wall and grounded. To record gastric mechanical activity at the site of electrodes, a fine silk thread was inserted and fixed into the muscular layer of the stomach, and the other end of the thread was connected to a strain gauge. Vagi were exposed and dissected free in the neck region, and the peripheral ends of the left vagus nerve were connected to a stimulator. Pulses of 0.1 msec. were delivered at 1-40 pulses/sec. Respiration was controlled by artificial respirator when necessary, and dogs were warmed by infrared lamp. Resting activity consisted of a rhythmic train of triphasic spikes (1 sec., 5-10 mV), each followed by a slow (5 sec.) spike potential of smaller amplitude. In most cases cervical vagotomy had no effect on electrical and mechanical activities of the stomach. Repeated high frequency vagal stimulation caused an increase in peristalsis of the stomach, an increase in duration and amplitude of the slow potential, and prolonged the intervals between potential changes. Atropine sulfate (0.02 mg/kg i.v.) gradually reduced mechanical activity, quickly abolished peristaltic movements, and markedly reduced amplitude of slow potentials. Not even atropine at a conc. of 0.1 mg/kg was sufficient to change the intervals between successive spikes. Effects of neostigmine bromide (0.2 and 0.5 mg/kg i.v.) were not consistent, although it generally increased the amplitude of the slow potential. Epinephrine (0.01 mg/kg i.v.) produced prolonged and irregular intervals between spikes in normal and atropinized stomachs. Tetrodotoxin (10^{-5} g/kg i.v. or by intra-arterial inj. at site of recording electrodes) abolished neither spike nor slow potential.

7907 ELECTROGASTROGRAPHIC CHARACTERISTICS OF GASTRIC MOTILITY DURING DIGESTION AFTER REMOVAL OF INTERVERTEBRAL NODES T6-T10. (Rus.) Sobakin, M. A. (Inst. Nutr., Acad. Med. Sci. USSR, Moscow) and N. P. Neverova. Eksp. Khir. Anest. 12(1):30-33, 1967.

Five dogs with a Basov gastric fistula were studied. When gastric innervation was preserved, the motor gastric function was characterized by a steady rhythm (5 waves/min.; the amplitude of the electrical waves varied from 2-6 mvolts) and strong peristaltic waves. Electrogastrographic study showed that removal of intervertebral ganglia at the level of the sixth-tenth thoracic segments depressed the strength of digestive motility (amplitude of electric waves decreased from 2-6 to 0.6-0.7 mvolts in 2 dogs), while the rhythm of the peristaltic waves remained unchanged. Such changes were preserved during 6 mo. of observation in 1 of 2 dogs, and in the other the strength of digestive motility began to be restored after 4 mo. but had not reached normal values even at 8 mo. In three other dogs, observed at 1 wk and at 1 or 2 mo., the decreased strength of digestive motility was somewhat less pronounced, and the rhythm remaine unchanged.

7908 A CONTRIBUTION TO THE STUDY OF THE RELATIONS BETWEEN MOVEMENTS OF CALCIUM AND THE HISTAMINE CONTRACTION OF SMOOTH MUSCLE. (Fr.) Carron, C. (Fac. Pharm., Paris). J. Physiol. (Paris) 59(1)(Suppl.):10-94, 1967.

An extensive study is made on the action of the Ca ion on the smooth muscle of the ileum of the guinea pig and the interaction of the Ca ion and histamine in the contraction of this smooth muscle. The part played by Ca in the contraction of smooth muscle *in vitro* in terms of the conc. and degree of ionization of Ca salts dissolved in the medium was the starting point. The results reveal certain new facts. The relationship between the amplitude of the histamine contraction of the isolated ileum of the guinea pig, the degree of ionization of Ca salts, and the Ca exchanges between the organ and its environment have been analyzed. It has been shown that the efflux of this element from the tissue is independent of the Ca content of the physiological soln. The influence of temperature and aeration upon Ca shifts was demonstrated. An increase in the movement of C from the intestine, in response to histamine, has been observed only if the Tyrode soln. contains some Ca. The disappearance of contractility of the isolated ileum following decalcification by sodium phosphate, and the recovery of contractility when the organ is replaced in a normal medium makes possible the demonstration of the specific role of exchangeable Ca ion, a phenomenon probably confined to the membrane. The part played by Ca ion in the mechanism of contraction may follow these stage (1) Histamine releases some Ca from some compartment in the vicinity of the membrane; this Ca diffuses into the external environment, ana also, on the other side of the membrane, towards deeper intracellular spaces; concomitan y histamine causes movement of Na and K, causing membrane depolarization and passage of the action potential. (2) The intracellular shift of Ca is towards the contractile elements of th smooth muscle fibers where adsorption produces contraction. (3) Reversal occurs during relaxation.

7909 NEW FINDINGS ON THE DISCHARGE OF VAGAL MECHANORECEPTORS OF THE INTESTINE. (Fr.) Mei, N. (Neurophysiol. & Psychophysiol. Inst., Marseille, France). C. R. Soc. Biol. (Paris) 160(12):2382-2387, 1966.

(2-4 kg) under anesthesia were used to
y the action potentials in the mechanorecep-
of the smooth muscle and mucosa of the
enum, jejuno-ileum, and large intestine
ciated with the intestinal plexi and afferent
lses in the vagus nerve. The appropriate
on of the intestine was opened in a suitable
ainer so that the temperature was maintained
7°C and the intestinal tissues retained their
al vascular and nervous connections.
lity of the intestine, the action currents,
ations of pressure in the intestinal wall
the pneumogram were simultaneously recorded.
r a receptor had been located and the
ous pick-ups (electrodes, etc.) were placed,
rdings were taken during 1) annular
trictions (3-5/min.) moving aborally
istalsis), 2) standing annular constrictions
ess amplitude than the preceding (about
in.) segmentation waves, and 3) the application
ight pressure. Spontaneous discharges of
anoreceptors were recorded; these coincided
pressure changes in the intestinal wall due
ontraction of the circular smooth muscle
er of the peristaltic or the segmenting type.
these action currents were not in motor
es was proved by the application of light
sure which caused a discharge of a train of
lses continuing for some time after cessation
ressure. Such receptors have been found in
duodenum, the jejuno-ileum and in the
imal ascending colon. The transmission of
e impulses in the vagus has been observed in
rs with a rate of conduction of 0.8-1 m/sec.,
ing these fibers in the C class. The
ptors in the mucosa do not ordinarily dis-
ge when the circular muscle beneath the
sa contracts; it is thought that they are
lly stimulated when the intestinal content is
ive or rough in the region.

SELECTIVE LOSS OF RESPONSIVENESS TO
ALPHA ADRENERGIC RECEPTOR STIMULATION
R COLD STORAGE OF THE RABBIT INTESTINE.
Lum, B. K. B. (Marquette U. Sch. Med.,
aukee, Wisc.), R. D. Heilman and M. A.
t. Europ. J. Pharmacol. 1(2):109-113, 1967.

ated segments of rabbit intestine (duodenal
ileal from the first and last 12 cm, resp.;
nal from sections more than 25 cm distal to
ach) were set up for recording of isotonic
itudinal muscle contractions. Responses to
athomimetic amines were measured in terms of
ction in tone produced by drug. Drugs were
wed to act for 1-2 min. before washout with
er's soln.; 5 min. was allowed to elapse
re the next dose; phentolamine (2.5 and 10 μg,
lenum; 5 and 10 μg, ileum) and pronethalol
& 40 μg, duodenum; 10, 20 & 40 μg, ileum) were
n. immediately after a preceding washout.
h preparations were used within 2 hr. of sac-
ce of animal; stored preparations were kept
00 ml Ringer's soln. at 6-8°C for 24 hr. or
. Dose ratios were calculated as follows: (ED$_{50}$
gonist in the presence of antagonist/(ED$_{50}$
of agonist in absence of antagonist). Intrinsic activity was calculated as (magnitude of max. response to sympathomimetic agent/(magnitude of max. response to norepinephrine). The drugs used were methoxamine, norepinephrine, epinephrine, nicotine, 1,1-dimethyl-4-phenylpiperazinium. Drugs were dissolved in physiological saline and soln. of catecholamines were acidified (0.2 ml HCl/100 ml) to retard oxidation of amines. With ileum and duodenum, the α-adrenergic blocking agent, phentolamine, antagonized the intestinal relaxation induced by methoxamine, an α-receptor stimulant, but not that produced by isoproterenol, a β-receptor stimulant. Opposite results were observed with pronethalol, a β-adrenergic blocking agent. This is consistent with the suggestion that stimulation of either α- or β-receptors can produce intestinal relaxation. Storage of duodenal and jejunal preparations reduced or abolished the intrinsic activity of methoxamine, but not that of epinephrine, norepinephrine, or isoproterenol. Cold storage impairs α-, but not β-, receptor activity. Ileum showed a greater resistance to cold storage.

7911 ACTION OF FUNCTIONAL TESTS ON INTEROCEPTIVE POSITIVE AND INHIBITORY CONDITIONED REFLEXES FROM MECHANORECEPTORS OF THE SMALL INTESTINE. (Rus.) Shapovalova, K. B. (Pavlov Inst. Physiol., Acad. Sci., Leningrad, USSR). Zh. Vyssh. Nerv. Deiat. Pavlov 16(5): 795-804, 1966.

Three dogs were provided with a Thiry-Vella fistula. Conditioning stimulants included light, electrical stimulation, bell and interoceptive stimuli (expansion of thin-walled rubber balloon in the lumen of an intestinal loop). Positive and inhibitory interoceptive conditioning reflexes displayed prolonged and marked changes after tests designed for interoceptive analysis and any change in stereotype; i.e., a special arrangement of light signal after release of exteroceptive differentiation did not influence positive and inhibitory exteroceptive conditioned reflexes, but produced a marked decrease of salivation on the interoceptive conditioning signal. Dogs with good mobility (exposed to tests directed toward exteroceptive analysis) showed that positive and inhibitory conditioned reflexes from mechanoreceptors of the small intestine differed by a certain degree of inertness, i.e., an exteroceptive positive stimulus, especially used at the site of exteroceptive differentiation, produced the usual result, while an interoceptive positive conditional stimulus at the site of interoceptive differentiation acted as an inhibitory signal. Poor conc. of the inhibitory process, produced by an interoceptive differentiating stimulus, was observed; i.e., during the prolongation of interoceptive differentiation, the latter was released, and all dogs showed marked consecutive inhibition after use in stereotypes of interoceptive differentiation. For example, if (after special admin. of a stereotypic signal, i.e., a light) consecutive inhibition was observed briefly (less than 1 min.), then the size of the conditioned reflex after interoceptive stimulus, used as a stereotype 4 min. after interoceptive differentiation, was markedly decreased; i.e., consecutive inhibition, interoceptively analyzed, was of a more prolonged and deep character.

7912 THE EFFECT OF H AND LACTATE IONS ON THE ELECTRICAL ACTIVITY AND CONTENT OF HIGH ENERGY PHOSPHATE COMPOUNDS OF TAENIA COLI FROM THE GUINEA PIG. (E.) Aaberg, G. (U. Gothenburg, Sweden), E. Mohme-Lundholm and N. Vamos. Acta Physiol. Scand. 69(3):129-133, 1967.

Reduction of the pH in Krebs soln. by 0.05-0.4 by adding lactic acid or acetic acid to a final conc. of 0.1-1.0 mmole/liter or by increasing the CO_2 conc. from 3-12% (pH change 0.28) in the gassing mixture caused relaxation of isolated taenia coli from the guinea pig. In determining the electrical activity of the membrane of the muscle by the sucrose gap method, it was found that a pH reduction inhibited the action potential, and with even lower pH values hyperpolarization was observed. In K-depolarized muscle a similar pH reduction had a tension-increasing effect. Na-lactate increased the electrical activity of the membrane and had a tension-increasing effect. The addition of lactic acid in a conc. of 1 mmole/liter, which relaxed the carbacholine-stimulated muscle had no effect on the content of high energy phosphate compounds. It seems probable that the relaxing effect of H ions was a result of its inhibitory effect on the electrical activity of the membrane.

7913 EFFECT OF GRAVITATIONAL AND INERTIAL FORCES ON PLEURAL AND ESOPHAGEAL PRESSURES. (E.) Rutishauser, W. J. (U. Minnesota, Rochester), N. Banchero, A. G. Tsakiris and E. H. Wood. J. Appl. Physiol. 22(6):1041-1052, 1967.

FETAL LIVER: A SOURCE OF IMMUNOGLOBULIN PRODUCING CELLS IN THE MOUSE. (E.) n, M. L. (U. S. Naval Radiol. Defense Lab., Francisco, Calif.), L. J. Cole and L. A. zenberg. Proc. Soc. Exp. Biol. Med. 124(4): l-1163, 1967.

lve-wk.-old thymectomized and nonoperated 7L x A)F_1 mice received 870 rad whole body rradiation and immediately thereafter were en an i.p. inj. of 33 x 10^6 nucleated cells ived from livers of 17-day (C57Bl/6 x C57Bl/6) ryos. Donor type γ-globulin was first detected small quantities 30 days after inj. of donor ls; by 45 days after irradiation, both the operated and the thymectomized mice had reciable quantities of donor type γ-globulin their sera. At 58 days all of the mice had rox. the same levels of donor and host type lobulins. Additional chimeras were produced ng fetal liver cells from 14-21 days (C57Bl/6 x Bl/6) embryos; all mice, thymectomized (21) well as intact (10) had significant amounts donor-type γ-globulins in their sera. These e sensitized to a synthetic polypeptide and ir sera were tested for total and (in 3 cases) donor-type anti-polypeptide antibody. All of fetal liver cell chimeras (intact thymus) proced specific antibody (10 of 10), but none of thymectomized chimeras (0 of 21) had detectle antibody. Of the 3 mice tested in the intactymus group, from 10%-75% of the specific antidy was donor in origin. These findings show at cells derived from fetal liver are capable producing γ-globulins whether placed in thyctomized or in intact irradiated hosts.

26 EXCHANGE OF INJECTED LABELED RED CELLS IN LIVER TISSUE DURING HEMORRHAGIC OCK. (E.) Andersen, D. (Cook County Hosp., icago, Ill.) and W. C. Shoemaker. Proc. Soc. . Biol. Med. 125(1):30-34, 1967.

e RBC content in liver was measured in normal d in shocked dogs using 2 independent methods measurement (radioassay, cells labeled with Cr, and chemical assay). The mean conc. of C in the liver of a series of animals under ntrol conditions was 0.027±0.002 ml/g liver ssue. After hypovolemic shock and retranssion of shed blood, the RBC content in liver ssue increased to an av. of 0.052±0.006 ml/g. is difference from control samples was gnificant. Under control conditions, the RBC bel of peripheral blood was mixed adequately th the RBC in liver tissues. After shock, fferentially labeled RBC mixed more slowly th the RBC in the liver, and in some instances d not become equilibrated during the course of e experiments. This suggested a pool of ncirculating or slowly circulating RBC in the ver after shock. Such changes may affect lversely the precision and interpretation of lood vol. measurements made by conventional echnics and sampling schedules.

7927 ACETYLCHOLINE IN THE CONTROL OF AMYLASE ACTIVITY IN PERFUSED, ISOLATED RAT LIVER. (It.) Brighenti, L. (U. Ferrara, Italy), C. Ottolenghi, L. Passerini and O. Barnabel. Boll. Soc. Ital. Biol. Sper. 42(24):1971-1975, 1966.

Isolated livers from adult, male rats, fasting 18 hr., were perfused with a liquid containing 15 ml washed rat RBC, 45 ml buffered Krebs-Ringer soln. (containing 5% crystallized bovine albumin) and 10 ml of a soln. containing 400 mg of acid hydrolysate of casein, 1 mg L-tryptophan, 3 mg tyrosine, 100 mg glucose, 5000 I.U. heparin, 6000 I.U. penicillin and 3 mg streptomycin. Addition of neostigmine (0.25 mg) plus acetylcholine (1.0 mg) to the perfusion liquid, repeated after 1 hr., increased the amylase activity of the liquid by approx. 100% as compared to a control, although neither substance alone exerted any appreciable effect. Inj. of actinomycin D into the donor animal (100 μg/100 g, 30 min. prior to sacrifice) plus addition of 100 μg to the perfusion liquid, completely inhibited the response to acetylcholine, indicating that the latter was mediated by some affect on RNA turnover. In a series of corollary experiments, addition of puromycin to the perfusion liquid (8 mg, repeated after 1 hr.) had no effect on amylase activity, of itself, but inhibited response to acetylcholine significantly, suggesting that the latter's stimulatory effect was linked to the synthesis of new protein molecules.

7928 GLYCOGEN SYNTHETASE ACTIVITY IN LIVER: REGULATION BY THE AUTONOMIC NERVES. (E.) Shimazu, T. (Osaka U. Med. Sch., Japan). Science 156(3779):1256-1257, 1967.

Under anesthesia, the left vagus nerve of rabbits was exposed immediately below the diaphragm, and a bipolar platinum electrode was placed on the nerve; after 15-20 min., one lobe of liver was quickly removed by ligation and was immersed in liquid nitrogen. Stimuli were applied to the vagus nerve (5 or 20 volts; 100/sec.; 3 msec.) or the splanchnic nerve (40 volts; 100/sec.; 3 msec.); after stimulation, the other lobe of the same liver was similarly removed while the stimulus was still being delivered. Total activity of liver glycogen synthetase, assayed in the presence of glucose-6-phosphate, was greatly increased by electrical stimulation of the vagus nerve, almost attaining max. within 5 min. The glucose-6-phosphate-independent activity of liver glycogen synthetase, assayed without glucose-6-phosphate, changed insignificantly before and after vagal stimulation. The increase in total activity after stimulation can be attributed to an increase in glucose-6-phosphate-dependent activity of the enzyme. The effect was completely counteracted by simultaneous stimulation of splanchnic nerves, although stimulation of splanchnic nerves alone had little effect on the enzyme. When anesthetized rabbits were inj. i.v. with insulin (2 U/kg) free of glucagon, both types of glycogen synthetase increased gradually during 15-20 min. after inj. The effect of vagal stimulation on glycogen synthetase activity of the liver is unlikely to be a secondary effect of insulin secreted from the pancreas, since pancreatectomized and intact rabbits gave essentially the same results. It is concluded that there is a dual regulatory system, hormonal and nervous, in glycogen metabolism in the liver, and that the nervous regulation is much more rapid than the hormonal.

7929 ANDROGENIC CONTROL OF A SEX-DEPENDENT PROTEIN IN THE RAT.

(E.) Roy, A. K. (Wayne State U. Sch. Med., Detroit, Mich.) and O. W. Neuhaus. Nature (London) 214(5088): 618-620, 1967.

A dependency of urinary proteins on the sex of the rat was demonstrated by paper electrophoresis. The α-globulin region, which is the chief protein component of male urine, is absent in the female urine. The urinary proteins of the normal female rats appear to be derived mainly from the plasma; the chief component migrated in a similar fashion to serum albumin. Ovariectomized rats, treated with 10-15 daily inj. of testosterone propionate (1 mg/100 g), excreted a new component which migrated in the same position as purified α_{2u} from male urine. Also demonstrated was the sex dependence of a liver protein which is precipitated by specific anti-rabbit antiserum; the protein was observed in the normal male liver, but not in that of the female. Earliest appearance of α_{2u} in the male liver occurred at 40 days (puberty) and also in the urine at this time. Normal daily excretion of α_{2u} in the male reached a max. of 63 mg daily by 60 days of age. Castration at this age reduced excretion to a minimum of 15-25 mg daily; castration before puberty yielded a low level of excretion, which reached 7-10 mg of protein by the time the rats were 60 days old. When these rats were given testosterone propionate (1 mg/100 g daily), a sharp increase to the normal α_{2u} excretion was observed after 8-9 days of treatment. Withdrawal of the testosterone after 80 days yielded a gradual reduction in the excretion of the protein. The action of testosterone appears to be an induction of an expression of normally repressed genetic information in terms of the synthesis of α_{2u} protein. Hepatic excretion of α_{2u} was completely abolished in males given 7 daily inj. of 1 mg estradiol dipropionate/100 g.

7930 A METHOD FOR DEMONSTRATING TRYPTOPHAN PYRROLASE ACTIVITY IN THE HUMAN LIVER.

(It.) Chiancone, F. M. (Lepetit S.p.A., Milan, Italy), E. Ginoulhiac, L. T. Tenconi and U. Bonomi. Acta Vitamin. (Milano) (6):225-234, 1966.

In 4-mo.-old Wistar rats, tryptophan pyrrolase activity in liver homogenates increased progressively and significantly when the liver was left in situ after sacrifice and the animal kept at room temperature for periods up to 18 hr Conversely, the activity was decreased sharply and progressively in homogenates stored at 2°C for as little as 4 hr. Both the rate and extent of loss were decreased when homogenates were frozen in dry ice. In human studies, no tryptophan pyrrolase activity was demonstrable in liver homogenates derived from 6 premature infants and stored in dry ice. Values ranged from 0.37-2.63 μmoles kynurenine/hr./100 mg nitrogen in homogenates derived from 5 of 6 neonates at term, with no activity demonstrable in the homogenate derived from the sixth. In homogenates derived from 3 adults, 25-40 yr. old values were zero, 1.01 and 1.37, resp. Identification of the enzyme was confirmed by a number of activation tests.

7931 PHYSICAL ACTIVITY AND LIVER CHOLESTEROL

(E.) Gollnick, P. D. (Washington State U., Pullman) and S. W. Simmons. Int. Z. Angew. Physiol. 23(4):322-330, 1967.

Male Sprague-Dawley rats were fed a synthetic rat diet consisting of lard, 24.2%; casein, 18.0%; sucrose, 13.4%; dextrin, 20.2%; salts, 1.7%; cod liver oil, 1.0%; agar, 3.3% and the known vitamins; water was added in the amount of 1.4 times the wt. of the dry constitutents. Food intake was controlled by pair-feeding the rats in groups of 4. In Experiment 1, 52 rats (av. initial body wt. approx. 320 g) were divided into 4 groups; 3 groups were trained for 12 wk. by swimming in water at 35°C for 15 min./day, 30 min./day and 60 min./day, resp. The fourth group served as unexercised controls. The latter gained significantly more wt. than exercised animals, whose absolute liver and spleen wt. was significantly less than controls. The adrenals of trained rats were heavier than controls. Nonexercised rats had higher liver cholesterol levels/g and also for total liver; increasing exercise beyond 15 min. did not produce a further reduction in liver cholesterol. Free plasma cholesterol was unaltered by training, while total plasma cholesterol was significantly lower only in the group of rats exercised 60 min./day. Exercised animals excreted significantly more sterol in feces than nonexercised controls. In a second experiment, rats (av. initial body wt. 90-100 g) were trained to run in motor-driven work wheels; during the initial 4 wk. the speed and duration of daily exercise were progressively increased until rats were capable of running for 60 min. at 1.0 miles/hr. Training was continued at this level for 4 additional wk. At the end of this period, 1 group of rats was removed from the training program, while a second group was progressively detrained for 4 additional wk. by reducing the exercise by 2 min./day; a third group of rats continued the daily 60-min. run throughout the entire experimental period, and a fourth group of unexercised rats were controls. The adrenals of all exercised groups were nificantly heavier than those of controls; ever, adrenals of those that detrained and sed to train were lighter than those of the up that trained the entire 12-wk. period at a n work load. Plasma cholesterol was not ered by any training program. Cholesterol c. in livers of the exercised groups was nificantly lower than that of controls; this nge seemed to be unstable since the difference ween the control group and the group that sed to train was not significant and the er cholesterol level of the determined group o appeared to be increasing. These findings icate that high fat diets produce a progressive umulation of cholesterol in the livers of s which can be retarded by exercise. The vated excretion of cholesterol (fecal sterol retion was significantly higher in trained s) may be one of the methods by which rcise retards the accumulation of cholesterol the livers of rats fed high fat diets.

2 INDUCTION OF NUCLEIC ACID SYNTHESIS OF THE LIVER DURING PARTIAL HEPATECTOMY PARABIOSIS. (Ger.) Wrba, H. (German Cancer . Ctr., Heidelberg, Germany), H. Rabes and G. er. Exp. Cell Res. 46(2):263-267, 1967.

parabiotic rats (250-300 g), after 4 days re was a definite anastomosis of the culatory systems; 4 days after parabiosis the t partner of 8 pairs was partially hepatectozed (67%); 4 other parabiotic pairs of rats rved as controls. The normal partners of the rabiotic rats and 1 partner of the parabiotic ntrols each received 100 μc thymidine-6-T, ecific activity 1.9 c/mM i.p.; the radiotivity of the blood of the parabionts was still ual 2 hr. after inj.; the liver was excised at hr. after radioactive thymidine inj. Radiotivity of the liver of the unoperated paraonts was compared to that of the controls. dioactivity av. 27 cells/10,000 counted cells the unoperated parabionts compared to 5.5 lls/10,000 of the controls. This av. was sed on liver samples taken from 2-96 hr. after ymidine inj. This induction of nucleic acid nthesis in the unoperated parabiont indicates me type ·f hormonal control of regeneration.

33 TRANSAMINASE ACTIVITY IN SUBCELLULAR FRACTIONS OF THE NORMAL AND REGENERATING T LIVER. (E.) Bengmark, S. (U. Goteborg, eden), R. Ekholm and R. Olsson. Acta epatosplen. (Stuttgart) 14(2):80-88, 1967.

e activities of glutamine-oxalacetic transaminase d glutamic-pyruvic transaminase in subcellular actions of the liver were studied before and 2, and 14 days after partial hepatectomy in male rague-Dawley rats; unmasking of latent enzyme tivity in the mitochondrial fraction was perormed using ultrasonic disintegration. In the ormal liver, glutamic oxalacetic transaminase as located as follows: mitochondrial fraction, 77.4%; microsomal, 2.4%; nuclear, 1.7% and supernatant, 17.9%; the glutamic-pyruvic transaminase activity was as follows: mitochondrial fraction, 10.5%; microsomal, 2.5%; nuclear, 1.7% and supernatant, 85.3%. There was a marked elevation of SGPT activity on the second postoperative day in partially hepatectomized rats; this was accompanied by a reduction of total glutamic-pyruvic transaminase activity of the liver (due, in turn, to a decrease in this transaminase in the supernatant). Activity of this transaminase in the mitochondria was largely unchanged. On the second postoperative day, when SGOT was enormously elevated, the total glutamic-oxalacetic transaminase activity of the liver was little affected. The rise of SGOT was accompanied by an elevation of glutamic-oxalacetic transaminase activity in the supernatant fraction; activity of this transaminase in the mitochondria was decreased. The elevation of SGOT activity cannot be explained by simple leakage from the liver, since total glutamic-oxalacetic transaminase activity/mg of liver tissue remained unchanged. It is suggested that there is an increased synthesis of glutamic-oxalacetic transaminase in the liver postoperatively; this may be a primary phenomenon or a response to a previous loss of enzyme from the cell. As in the normal liver, transaminase activities in the nuclear and microsomal fractions of the regenerating liver were very low, and no significant changes that could be ascribed to the partial hepatectomy were observed.

7934 EFFECTS OF ADRENAL HORMONES UPON DNA SYNTHESIS IN REGENERATING RAT LIVER AND TUMORS. (E.) Sakuma, K. (U. Tokyo) and H. Terayama. J. Biochem. (Tokyo) 61(4):504-511, 1967.

In rats pretreated with cortisone (5 mg/day for 5 days before partial hepatectomy), the increase in DNA synthesis which normally occurs during the course of liver regeneration was greatly retarded, as was induction of the enzymes thymidine kinase and thymidylate kinase. Admin. of epinephrine (15-25 μg/hr. for 24 days) was also effective in inhibiting DNA synthesis and thymidine kinase induction in regenerating livers, but no such effects were produced with hepatoma cells. Whereas cortisone was effective when admin. repeatedly before partial hepatectomy in large doses, epinephrine was most effective when given in small quantities during an early period of liver regeneration, during which time the induction mechanism would still be operating; this effect was reduced when epinephrine was admin. later than 24 hr. after partial hepatectomy. It is suggested that the action of epinephrine may be more direct than that of cortisone, and that it may be acting at a stage preceding the S phase, probably at the "dichophase", of the mitotic cycle. Since cortisone is very effective in producing involution of lymphoid tissues and certain lymphoid cells play a role in tissue proliferation, it is possible to assume the reutilization of lymphocyte DNA by tissue cells undergoing regeneration. Therefore, the observed effects of cortisone may be explained as being due to its primary action upon the lymphoid tissues.

7935 HUMORAL CONTROL OF LIVER REGENERATION. (E.) Sigel, B. (Woman's Med. Coll. Pennsylvania, Philadelphia), L. B. Baldia, M. R. Dunn and H. Menduke. Surg. Gynec. Obstet. 124(5):1023-1031, 1967.

Studies were performed in order to evaluate several aspects of a hypothesis stating that liver regeneration is humorally controlled. The parabiotic rat preparation, in which 1 animal is submitted to partial hepatectomy and the livers of the nonoperated upon or both members of the pair are examined, has been the most frequently used method of studying humoral relationships in liver regeneration *in vivo*. However, in this study an experimental preparation was devised which was basically similar to rat parabiosis (in that liver tissue existed at 2 separate loci in the same biologic system), but which obviated some of the disadvantages of the parabiotic system. Mongrel dogs of both sexes underwent 2-stage autotransplantation of a portion of the left central liver lobe to an intestinal pedicle, and the effect of partial resection, Eck fistula, combined partial resection and Eck fistula, and sham operation upon the transplanted liver was observed on the grafts. Hepatocyte DNA synthesis was studied by admin. of tritiated thymidine and autoradiographic analysis. Hepatocyte DNA synthesis was found to be markedly increased in grafted as well as nontransplanted liver after partial hepatectomy, but no significant change in DNA synthesis at either site could be associated with Eck fistula. There was a significant correlation between the rate of hepatocyte DNA synthesis in the graft and its parent liver tissue. The combination of partial hepatectomy and Eck fistula resulted in extensive hepatocyte DNA synthesis in the nontransplanted liver remnant; and the effect of partial hepatectomy and Eck fistula upon the nontransplanted liver was greater than after partial hepatectomy alone, but not significantly so. It is concluded that after partial hepatectomy (partial liver resection), hepatocyte DNA synthesis appeared to be mediated by a humoral mechanism and not by hepatic blood flow.

7936 BILE ACID SYNTHESIS IN NORMAL AND HYPOPHYSECTOMIZED RATS: A RATE STUDY USING CHOLESTYRAMINE. (E.) Beher, W. T. (Henry Ford Hosp., Detroit, Mich.), B. Rao, M. E. Beher and J. Bertasius. Proc. Soc. Exp. Biol. Med. 124(4):1193-1197, 1967.

Twelve normal and 16 hypophysectomized, 6-mo.-old, Sprague-Dawley female albino rats were studied. The 12 normal animals were divided into 3 equal groups; 1 group, the controls, was fed ground Rockland rat rations, while the other 2 groups received the same diet supplemented with 1% and 2% cholestyramine (a nonabsorbable, bile acid-binding, anionic exchange resin added to increase the turnover rate of the bile acid pool). The hypophysectomized animals were divided into 4 equal groups; 3 of these received diets corresponding to those fed the normal rat groups, and a fourth received Rockland rat rations supplemented with 0.5% cholestyramine. After 1 wk. each received an i.p. inj. containin 5 μc (56 mc/mM) of cholic acid-24-^{14}C dissolved in 0.9% $NaHCO_3$. Either of 2 sequences involved in the elimination of tissue sterol by the bile pathway could be rate-limiting: 1) the conversi of sterols to bile acids, and 2) elimination of these bile acids from their pool. The bile acid pool sizes did not decrease when faster turnover rates were induced (by the action of cholestyramine); thus, the rate of bile acid elimination and not the rate of conversion of liver sterols to bile acids was found to be the rate-limiting sequence in both types of rats. It is concluded that thyroid, adrenal, gonadal or pituitary hormones do not directly influence the rate of conversion of sterols to bile acids in this species.

7937 THE EFFECT OF PORTACAVAL TRANSPOSITION ON THE INACTIVATION OF ANGIOTENSIN BY THE CANINE LIVER. (E.) Schwartz, D. T. (Columbia U., New York, N. Y.). Ann. Surg. 166(1):157-160, 1967.

The capacity of the canine liver to inactivate synthetic 1-L-asparaginyl-5-L-valyl angiotensin amide was measured by the pressor response to its infusion. This parameter was measured in normal dogs, and in those with portacaval transposition alone, renal artery stenosis alone, or both in combination. The pressor response to single inj. of angiotensin into the systemic vein was compared with pressor response to the same dose given across the liver. The capacity of the liver of normal dogs to inactivate angiotensin was 0.55±0.05 μg, when the dose was admin. in 10 sec.; the activity did not change significantly after portacaval transposition. The angiotensin-inactivating capacity of the liver of dogs with a renal artery stenosis and sustained arterial hypertension was measured as 0.66 μg angiotension, which was not significantly greater than the capacity of the normal liver to inactivate angiotensin. In dogs with renal artery stenosis and portacaval transposition, however, there was a significant increase in the capacity of the liver to inactivate angiotensin. At 3 wk. after constriction of the renal artery, 0.75 μg were inactivated, while after 1 yr., the capacity was 1 μg or approx. twice the normal. It is suggested that portacaval transposition performed in patients with chronic renal disease and hypertension may continue to protect against the latter, even if the renal disease progresses, once the blood pressure was initially brought to normal.

CONGRUENCE OF EXCRETORY FUNCTIONS OF LIVER AND KIDNEY: SULFONAMIDES. (E.) popoulos, A. (U. New Mexico Sch. Med., uquerque) and H. Sonnenberg. Amer. J. Physiol. (5):1117-1122, 1967.

retion of 20 sulfonamides by isolated perfused livers was compared with reported behavior the same compounds in renal excretory proses. Extensive metabolic alteration of most pounds by liver was demonstrated. Metabolites e isolated and examined for participation in al transport. In general, compounds that e actively transported by kidney were highly c. in hepatic bile. In both organs the retory process could be inhibited by benecid (0.05 mM). Conversely, compounds that e not transported by kidney were poorly conc. hepatic bile. In both organs excretion of h compounds was uninfluenced by probenecid. is concluded that liver and kidney possess a ilar mechanism for excretory transport of anic anions such as sulfonamides and that strate specificities for transport are ntical in the two organs.

9 HEPATIC MICROSOMAL ACTIVITIES IN RATS WITH LONG AND SHORT SLEEPING TIMES ER HEXOBARBITAL: A COMPARISON. (E.) Mitoma, (Stanford Res. Inst., Menlo Park, Calif.), E. Neubauer, N. L. Badger and T. J. Sorich, Proc. Soc. Exp. Biol. Med. 125(1):284-288, 7.

s (5 strains: Buffalo, Wistar, Fischer, g-Evans and Sprague-Dawley) were separated o 2 groups, long-sleepers and short-sleepers, the basis of their response to hexobarbital 0 mg/kg, admin. i.p.). The drug-metabolizing ivities of the hepatic postmitochondrial ernatant fraction from long-sleepers were s than those from short-sleepers with respect hexobarbital, acetanilide, aminopyrine and itroanisole, each of which represents a fferent drug-metabolism pathway; this trend observed in all 5 rat strains examined cept in the metabolism of o-nitroanisole by e Fischer rats. This difference was no longer served in Long-Evans rats after phenobarbital etreatment (only acetanilide and aminopyrine re tested). The livers of Wistar and Fischer ts showed the highest and Buffalo rats the west drug metabolizing activities among the 5 rains studied. The strain differences in ug-metabolism activities were not as great in e rat as those previously reported in various bbit strains. These findings are confined to ose drugs detoxified oxidatively by the ver microsomes.

40 MAXIMUM BILIARY EXCRETION OF BILIRUBIN AND SULFOBROMOPHTHALEIN DURING ESTHESIA-INDUCED ALTERATION OF RECTAL TEMPERARE. (E.) Roberts, R. J. (U. Iowa Coll. Med., wa City), C. D. Klaassen and G. L. Plaa. Proc. Soc. Exp. Biol. Med. 125(1): 313-316, 1967.

The influence of temperature on the max. biliary excretion of bilirubin and BSP was studied in anesthetized (pentobarbital; rats, 45 mg/kg, i.p.; mice, 80 mg/kg., i.p.) male Swiss-Webster mice and male Sprague-Dawley rats. Bilirubin soln. were infused at a rate of approx. 0.07 and 0.02 ml/min. in rats and mice, resp. BSP (50 mg/ml) was diluted in sufficient 0.9% NaCl to permit an infusion of approx. 0.03 ml/min. Mice showed a more rapid and greater fall in rectal temperature than rats after pentobarbital anesthesia, dropping approx. 10°C in 60 min.; rats showed a drop of 2.5°C over the same period. A decrease in body temperature significantly decreased the bilirubin transport max. in both rats and mice; a loss of body temperature in the rat also produced a significant decrease in the BSP transport max. In both rats and mice, bile flow showed a diminution corresponding with the decrease in rectal temperature. Bile flow and biliary transport max. data for bilirubin and BSP suggest that, in the rat, temperature has a greater effect on bile flow than on biliary excretion. This differential effect was more evident in bilirubin studies performed on mice; here, while bile flow diminished with hypothermia, the biliary conc. of bilirubin increased significantly. These observations lend support to the suggestion that formation of bile is a consequence of at least 2 separate mechanisms: 1 controlling the introduction of water and electrolytes, and the other controlling the active secretion of specific substances into the bile. The results of these experiments emphasize the importance of monitoring body temperature during the course of experiments employing max. biliary excretion as an endpoint.

7941 EFFECT OF ADRENALCORTICAL HORMONES ON RELEASE OF TRIGLYCERIDES AND GLUCOSE BY LIVER. (E.) Klausner, H. (Vanderbilt U. Sch. Med., Nashville, Tenn.) and M. Heimberg. Amer. J. Physiol. 212(6):1236-1246, 1967.

The uptake of free fatty acid and release of glucose, triglyceride, urea and ketone bodies by the isolated perfused (Sprague-Dawley) rat liver were measured, employing livers from normal or adrenalectomized animals, or from animals treated with cortisone. Release of glucose and triglyceride was depressed and output of ketone bodies was moderately stimulated after adrenalectomy. Uptake of free fatty acids and output of urea were not altered by adrenalectomy. When the adrenalectomized animal was treated with cortisone, the triglyceride and ketone body output was restored to normal values and the release of glucose was stimulated. Cortisol, added to the medium in vitro, stimulated output of triglyceride and glucose by the liver. A critical conc. of hormone was attained, below which there was no stimulation and above which there was inhibition of triglyceride release.

At this conc., cortisol stimulated triglyceride output by livers from normal rats and increased the depressed rate of triglyceride output observed with livers from adrenalectomized animals. This same amount of cortisol induced the max. output of glucose by livers from normal rats.

DEGREE OF FLUORESCENCE IN THE PROGNOSIS
OF MALIGNANT TUMORS. (E.) Rachlin, L.
Hosp., Livermore, Calif.) and J. R. Harrower.
. J. Dig. Dis. 12(6):593-597, 1967.

0 patients studied for the presence of
racycline fluorescence in gastric and colonic
irates, there were 12 with confirmed gastric
ignancy and 18 with colonic malignancy. In
12 cases of gastric cancer, there were 7 (58%)
e-positive and 5 (42%) false-negative tests.
the 18 colon cancer cases, there were 10 (56%)
e-positive and 8 (44%) false-negative tests.
re were 15 cases of benign gastric lesions,
h 12 (80%) true-negative and 3 (20%) false-
itive tests. The 5 benign colon lesions
wed 2 (40%) true-negative and 3 (60%) false-
itive tests. In the total 50 cases, there
e 30 (62%) true tetracycline fluorescent
ts and 19 (38%) false tetracycline fluorescent
ts. There was no apparent relationship between
degree of fluorescence, as measured by the
tomicrographic sensing unit, and the extent
involvement by the tumor, as noted at the time
surgery or autopsy. The range of color in-
sity appeared to be totally inaccurate, since
greatest intensity (23.4) was recorded in a
se-positive test, and the av. for true-positive
sults was 5.9, just 5.3 U from the lowest color
tensity of 0.6, as noted at the time of surgery
autopsy. It is thought that the tetracycline
uorescence test as a screening procedure for
lignancies of the stomach and colon is of
estionable value, since the percentage of false
sts (both positive and negative) is too high.
e diagnostic unreliability and time involved in
eparation for the examination preclude the use
the tetracycline fluorescence test as a mass
reening test in the diagnosis of either gastric
colonic cancer.

85 ANGIOGRAPHY IN THE DIAGNOSIS OF
GASTROINTESTINAL BLEEDING. (E.) Baum,
(U. Pennsylvania Grad. Hosp., Philadelphia),
Nusbaum, K. Kuroda and H. J. Tumen. Arch.
tern. Med. (Chicago) 119(1):16-24, 1967.

dominal angiography gave positive information
the source of hemorrhage in 18 of 21 patients.
is technic is effective only when the patient
actually bleeding at a rate of more than 0.5
/min. at the time of examination. It may show
hat bleeding is occurring, but it may not reveal
he nature of the bleeding lesion. This method
ust be supplemented with other methods, although
are should be taken to perform angiography before
a examination, since Ba in the gastrointestinal
ract obscures angiography interpretation.
ngiography is safe and does not interfere with
ther methods of examination or delay urgent
urgery; it appeared to be especially valuable
n studying patients with cirrhosis (and intes-
inal bleeding), and esophagogastric varices.
elective abdominal angiography seems particularly
well adapted to discovering other than the obvious source of a hemorrhage, i.e., other lesions and varices.

7986 AN AUTOMATIC CARTRIDGE STAPLER. (E.) Cooper, P. (Albert Einstein Sch. Med., Bronx, N. Y.), R. F. Mallina and S. H. Tolins. Amer. J. Surg. 113(6):856-860, 1967.

An automatic stapler capable of individually dispensing 15 plastic staples from a presterilized, disposable cartridge is described and was sucessfully used in making secure anastomoses, closures and repairs in laboratory animals and human subjects. No complications occurred in the patients; stapling was used for the first layer of a duodenal stump closure, and for a common iliac arteriotomy closure. The instrument was set in a ring-handled hemostat frame, and in a tissue forceps frame. Neither form is significantly larger or heavier than those frames ordinarily used in surgery. Two staple sizes are available; one is 0.15 mm in diameter, 2 mm in width, and with a leg length of 2.5 mm; the other is 0.22 mm, 3 mm, and 3.5 mm. This individual stapler, unlike those which inject all staples in one line at once, allows the surgeon to follow any contour desired.

7987 STUDIES ON THE NUMBER AND TYPE OF ENZYMES OF THE GASTRAL, INTESTINAL AND RECTAL MUCOSA IN MAN. PART 3. ELECTROPHORETIC DIFFERENTIATION OF INTESTINAL ENZYMES AND THEIR MULTIPLE FORMS AND A COMPARATIVE ANALYSIS OF SERUM ENZYMES. (Ger.) Klein, U. E. (U. Clin. Kiel, Germany), H. C. Drube, H. T. Hansen and H. Mielke. Klin. Wschr. 45(5):244-251, 1967.

Patients operated for ulcer or carcinoma furnished mucosal tissue: 10 from the gastric fundus, 12 from the duodenal bulb, 9 from the first jejunal loop. Biopsies furnished tissues: 4 from the duodenum, 4 from the jejunum and 8 from the rectum of subjects without any gastrointestinal disorders. The tests for enzymes were undertaken on fresh tissue or tissue frozen at -20°C for as long as 2 wk. The mucosa was cut into frozen sections for histochemical demonstration of some enzymes; other enzymes were studied in homogenates derived from the mucosal tissue. The enzymes in the supernatants of the homogenates were separated by electrophoresis in acrylamide gel at different pH values. Some enzymes were identified by differential staining of the gel; these were unspecific esterases, LDH, alkaline phosphatase, and leucine aminopeptidase. These enzymes were identified in the sera of normal persons and the sera of persons with liver cirrhosis using the same means. In all parts of the gastrointestinal tract numerous water-soluble esterase fractions were found; these were a group moving anodally, some slowly and some rapidly. The esterases of normal serum did not coincide with any of the gastrointestinal esterases, at least with respect to their migration velocities. The LDH fractions I-V showed different, characteristic conc. in the various divisions and subdivisions of the tract. Contrary to results of histochemical tests, leucine aminopeptidase activity was found in homogenates of the mucosa of stomach and rectum; 3 anodally-moving leucine aminopeptidase fractions with different staining intensities were found in different parts of the gastrointestinal tract; 1 fraction from the mucosa coincided with 1 fraction from the serum. Alkaline phosphatases of the small intestine could be separated into 3 fractions in the jejunum; 1 fraction could be detected in all parts of the gastrointestinal tract; in addition to a normal serum phosphatase this fraction was found in the serum of patients with cirrhosis of the liver. This is the only enzyme analyzed and so far clearly identified in the serum.

7988 COMPLICATIONS IN PERITONEOSCOPY AND THEIR PROPHYLAXIS. (Rus.) Vasiliev, R. K. (Hosp. No. 1, Moscow). Sovet. Med. 30(2): 87-91, 1967.

A total of 642 cases of complications (including the author's) which occurred during the initial stages of peritoneoscopy (establishment of pneumoperitoneum) were found in Soviet and foreign literature. The following complications were found (number of cases in parentheses): subjective sensation of the patient, s.c. emphysema of the abdominal wall while treating pneumoperitoneum (137), acute development of ascites (62), mediastinal emphysema (48; 2 of which were fatal), emphysema of the greater omentum (38), puncture of the genital organs (26; 1 of which was fatal), large hematomas of the abdominal wall (28), collapse during establishment of pneumoperitoneum (20), air embolism (8; 6 of which were fatal), shock at peritoneoscopy (6), and 1 each of epileptic status at congenital epilepsy, emphysema of the intestinal wall, valvular pneumoperitoneum, strangulation of femoral and diaphragmatic hernia and puncture of bladder and hydronephrotic kidney. Prophylaxis of the complications is discussed. Complications (35) found while conducting peritoneoscopy (including the author's data) were internal hemorrhages (12), intestinal puncture, puncture of genital organs (7), infrequent torsion of the omentum about the peritoneoscope, strangulation of fatty intestinal suspension in the opening of the trocar membrane, and entrance of hernial content with puncture of the latter, introduction of optics into the hepatic parenchyma and prolapse of the omentum after removal of the trocar with optics. During 140 peritoneoscopies on patients (3-82 yr. old) with various surgical, therapeutic and gynecological diseases, emphysema of the abdominal wall was found in 5, emphysema of the greater omentum in 1 and hematoma of the abdominal wall with late suppuration (after 3 mo.) in 1. There were no fatal outcomes. Reasons for damage to mesenteric vessels, liver and omental vessels are discussed.

7989 STUDY OF THE METABOLISM OF TRYPTOPHAN IN VARIOUS HEPATO-DIGESTIVE DISEASES. II. FREQUENCE OF ANOMALIES IN NEOPLASTIC DISEASES. (Fr.) Lemonnnier, A. (St. Antoine Hosp., Paris), F. Lemonnier, B. Chevrel, C. Charpentier and J. Caroli. Rev. Franc. Etud. Clin. Biol. 12(2):162-169, 1967.

The metabolism of tryptophan was studied in 103 patients with 3 general types of disorders: 35 had cancer (11 pancreas, 11 liver, and 14 miscellaneous); 33 cirrhotics (17 alcoholic, 6 biliary cases and 2 with hemochromatosis); 35 h 1 of 7 different disorders of the digestive tra The metabolites of 5 g tryptophan p.o. were determined in the 24-hr. urine, chiefly by paper chromatography. Of the cases of cancer, 27 (77 showed an abnormal excretion unrelated to distribution of the neoplasms. Among the 33 with cirrhosis, 9 subjects (27.3%) had disturbed tryptophan metabolism. In the general group of 35, 9 (25.7%) had faulty excretion. The metabolites measured were kynurenine, and xanthurenic, cyanurenic and anthranilic acids; tryptophan metabolism was considered abnormal wh 1 or more of these was present in the urine in amounts above the normal range. The etiology and mechanisms of these alterations are uncertain. The B-group of vitamins, especially pyridoxal phosphate and riboflavin, may be involved, inasmuch as in a large proportion of ca with faulty tryptophan metabolism, there were deficiencies in 1 or both.

7990 EXTRAPERITONEAL TREATMENT OF ABDOMINAL ORGANS WITH SOAP AND WARM WATER IN EXPERIMENTAL PERITONITIS. (Rus.) Flat, K. L. (Altai Med. Inst., Barnaul, USSR). Eksp. Khir. Anest. 12(1):33-35, 1967.

A study was made on 60 dogs (20/series) which we divided into 3 groups according to the site of t perforation opening (which was 0.5 cm in diamete Group 1, perforation in the anterior wall of the antrum; Group 2, perforation in the medial portion of the jejunum; and Group 3, perforation in the cecum. At relaparotomy 24 hr. later, purulent peritonitis was found; the abdominal organs were treated extraperitoneally with soap and warm water, the intestinal opening was close streptomycin and penicillin in 25% novocain soln were admin. and the incision was closed. During the postsurgical period, all animals received a 20% soln. of camphor oil, streptomycin and penicillin. A fecal mass (25 g/kg body wt.) was introduced into the perforation in order to approach clinical experimental conditions. In Group 1, all dogs were cured by the soap treatment. Fever was less pronounced, the duration o fever was shorter (av. 4.37 days), wt. loss was less (av., 0.9 kg) and recovery occurred more quickly (av., 8.7 days) than in untreated contro In Group 2, in dogs treated with soap the wt. loss and intoxication were less, temperature returned to normal earlier, leukocytosis was less pronounced and was restored more quickly,

ecovery occurred 7.1 days earlier than in
rols. The clinical course of peritonitis
roup 2 animals was more favorable than in those
roup 1. In Group 3, after treatment with
hyperemia of abdominal organs was increased,
serous tegmentum became rose-colored and
nt, local leukocytosis, phagocytosis and
toneal resistance increased, and gastric and
stinal peristalsis was activated. The number
acteria was markedly decreased by soap
tment, and it is concluded that soap treatment
eritonitis should be included among the ac-
ed methods for the treatment of peritonitis.

SILICONE FLUID IN THE PREVENTION OF
INTESTINAL ADHESIONS. (E.) Frey, C. F.
Michigan Med. Ctr., Ann Arbor), C. Thorpe and
rody. Arch. Surg. (Chicago) 95(2):253-256,

gue-Dawley rats were divided into 3 control
ps and 3 groups which received silicone
tment; controls consisted of 1) those re-
ing celiotomy alone; 2) those receiving
otomy and silicone fluid with a viscosity of
350 and 1000 centistrokes; and 3) celiotomy
abrasion of the intestines with sandpaper.
the experimental group, animals received
iotomy, abrasion of the intestines and silicone
id having a viscosity of 20, 350 and 1000
tistrokes. Silicone fluid was used in an ef-
t to prevent development of intestinal adhes-
s. Group 1 of controls had no intestinal ad-
ions when examined at sacrifice. Groups 2 and
eveloped adhesions. All animals that received
icone fluid in the experimental group also
eloped adhesions. Adhesions in silicone-
ated animals were more vascular and thicker
n in controls. Granuloma formation was also
ed in the silicone-treated rats, but not in
trols.

92 ANASTOMOSES IN THE ALIMENTARY TRACT
USING A SERO-MUSCULAR TUBULAR CUFF
HNIC. (E.) Lindenmuth, W. W. (Yale U. Sch.
., New Haven, Conn.) and C. J. May. Ann.
g. 165(4):590-597, 1967.

oux-en-Y loop of jejunum was prepared in 12
s by excising the mucosa of the proximal seg-
t for a distance of 1.5-2 cm. The loop was
ught into the chest through an incision in
e diaphragm and anastomosed to the proximal
ansected esophagus, the distal esophagus having
en closed. Four traction sutures (000 chromic
tgut) were placed equidistant around the cir-
mference to guide approximation of the esophagus
the edge of the mucosa-submucosa within the
junal tube. The full thickness of the esophagus
s sutured to the jejunal mucosa and submucosa.
ch of the 4 guide sutures then approximated a
adrant of the circumference of the esophagus
jejunal mucosa-submucosa. Usually the muscle
yer of the jejunum was included in the sutures,
t serosa was avoided. The seromuscular flap
of jejunum was sutured to the external wall of the esophagus. Four dogs developed mesenteric thrombosis soon after operation and died; 1 died because of gangrene of the loop but the seromuscular cuff was viable and firmly attached to the esophagus; the anastomosis leaked in 1 animal in which there was early gangrene; the 4 who survived 2-4 mo. had no anastomotic strictures. Microscopically there was good healing between the esophageal and jejunal muscle layers with minimal scarring. Leakage and stenosis were not observed. In 27 patients, various types of procedure using the seromuscular tubelike cuff technic for anastomosis were tried, using cuffs of stomach, duodenum, and ileum in this easier and safer anastomosis: esophago-enterostomy, 10; pancreatic-cystojejunostomy (intra), 3; choledochojejunostomy (extra), 5; esophagogastrostomy, 1; ampullary jejunostomy, 1; duodenal stump closure, 7. Case histories are given of 6 patients who had complications related to the operation.

7993 DOUBLE-BLIND TREATMENT STUDY OF SHIGELLOSIS COMPARING AMPICILLIN, SULFADIAZINE, AND PLACEBO. (E.) Haltalin, K. C. (Southwestern Med. Sch., Dallas, Tex.), J. D. Nelson, R. Ring, III, M. Sladoje and L. V. Hinton. J. Pediat. 70(6):970-981, 1967.

Infants and children (52) hospitalized for shigellosis were admin. ampicillin, 100 mg/kg daily, sulfadiazine, 120 mg/kg daily, both p.o. A loading dose of one half the total daily dose was given for the initial dose; subsequent doses were admin. every 6 hr. for 5 days. Rectal swabs were made daily; in vitro susceptibility to ampicillin and sulfadiazine were determined by a plate dilution method on all Shigella isolates from each patient; SGOT determinations were made before and at the end of therapy in 46; routine complete blood counts and serum electrolyte determinations were done on admission and repeated as necessary. Of the 52, 18 received ampicillin, 18 sulfadiazine, 16 placebo. Bacteriological failure rates in patients treated with placebo and sulfadiazine were 75% and 39%, resp., compared with 6% in those receiving ampicillin. Clinical failure was observed in 56% of placebo patients, 39% of sulfadiazine patients, and none of the ampicillin patients. It is concluded that ampicillin is a safe and highly effective drug for the treatment of shigellosis.

GASTROINTESTINAL DISEASES

GENERAL

8025 DIAGNOSIS OF ULCEROGENIC TUMOR OF THE PANCREAS BY BIOASSAY. (E.) Moore, F. T. (Ohio State U. Sch. Med., Columbus), J. E. Murat, G. L. Endahl, J. L. Baker and R. M. Zollinger. Amer. J. Surg. 113(6):735-737, 1967.

Adult male rats (Wistar strain), bearing a total gastric fistula, were used in the preoperative differential diagnosis of suspected ulcerogenic tumor of the pancreas. Ten of 139 patients (aged 30 to 67 yr., 7 men and 3 women) responded positively to such bioassay of the serum, gastric juice or urine for gastric acid secretagogue activity. The diagnosis was histologically confirmed in each case. Among 129 subjects who gave negative bioassay responses were: 45 cases of duodenal ulcer, 5 of gastric ulcer, 52 of marginal ulcer, 5 of enteritis, 3 of bronchial adenoma, 3 of post-shunt hepatic cirrhosis, 16 normals. Diagnoses were made after surgical exploration. The authors stress the reliability of the technic described as a bioassay for ulcerogenic pancreatic tumors.

8026 VARIABILITY OF GASTRIC SECRETION IN PATIENTS WITH AND WITHOUT THE ZOLLINGER-ELLISON SYNDROME. (E.) Winship, D. H. (Marquette U. Sch. Med., Milwaukee, Wis.) and E. H. Ellison. Lancet 1(7500):1128-1130, 1967.

Repeated histamine stimulation tests and 12-hr. (overnight) measurements of basal acid secretion were made in 8 patients with severe, recurrent peptic ulcers (a 14-yr.-old boy and 3 men, 4 women, aged 26-68 yr.). Results suggested the presence of Zollinger-Ellison syndrome in all cases, although this tentative diagnosis was confirmed histologically, at the time of surgery, in only 4 of 8 (including 1 of 8 in whom histamine stimulation could not be repeated, due to hemorrhage requiring emergency surgery; 1 of 8 in whom basal acid secretion studies had been positive but histamine stimulation studies had appeared to be negative). In all patients, gastric secretory patterns showed striking variations in terms of the absolute values which were tabulated at different times. This was especially marked in the case of basal acid secretion levels. Among the patients in whom the syndrome was confirmed, 3 of 4 had metastatic carcinoma of the pancreatic islet cells; 1 of 4 had microadenomatosis of the pancreatic islets. Among the patients in whom the syndrome was not confirmed, 1 of 4 was suffering from a large gastric ulcer; 3 of 4 had active duodenal ulcers. Note is made that the pancreatic tail was not resected for diagnostic purposes, in this last group of patients, so that the presence of the syndrome was not, in fact, completely excluded.

8027 ISLET CELL TUMOR OF THE PANCREAS WITH REVERSIBLE WATERY DIARRHEA AND ACHLORHYDRIA. (E.) Marks, I. N. (Groote Schuur Hosp., Capetown, South Africa), S. Bank and J. H. Louw. Gastroenterology 52(4):695-708, 1967.

A 34-yr.-old male with a metastasizing non-β-is cell tumor of the pancreas with intractable wat diarrhea (16-yr. duration), hypokalemic acidosi hypercalcemia, and achlorhydria is presented. Resection of the primary tumor induced a transi partial remission of the diarrhea and a return acid secretion, and steroid therapy (initially 300 mg hydrocortisone hemisuccinate daily; late decreasing doses of prednisone to 12.5 mg daily given during a subsequent relapse, resulted in dramatic cessation of the diarrhea and a striki increase in acid secretion. The pathological features of the above syndrome are virtually id tical with those of the Zollinger-Ellison syndr Gastrin-like substance could be demonstrated in the latter, not in the former. The Zollinger-Ellison syndrome is characterized by marked aci hypersecretion, intractable peptic ulceration, possible steatorrhea or diarrhea; the other syndrome by watery diarrhea, the effects of water and electrolyte loss, hypochlorhydria or achlorhydria. A large number of patients showe mixed features. In the above case the possibil exists that the islet cell tumor was responsibl for the severe attacks of intermittent diarrhea which started in 1955, and that the diarrhea became intractable only after metastatic spread had already occurred. It is concluded that thi syndrome is a specific entity distinct from the clinical variants of the gastrin-induced Zollin Ellison syndrome.

8028 HYPERCALCAEMIA AND GASTRIC HYPERSECRE IN THE FAMILIAL ENDOCRINE-ADENOMA SYNDROME. (E.) Kerr, G. D. (Waikato Hosp., New Zealand) and R. Smith. Lancet 1(7499):1074-107 1967.

Five hyperparathyroid patients in 3 generations of the same family with the multiple endocrine adenomatosis syndrome, i.e., with 1 or more endocrine adenomas, were studied to determine any possible relation between gastric hypersecr tion and hypercalcemia in 2 of the patients; these 2 sisters had gastric hypersecretion, wit subsequent total gastrectomy and parathyroidect The ages and sex of the 5 patients were: 54 (woman), 39 (woman), 36 (woman), 33 (man), and 14 (boy). Each of the 5 showed different featu of the familial syndrome. Laboratory studies included basal and stimulated gastric secretion (initial, after phosphate, and after parathyroi ectomy), plasma Ca, and P. It seemed that the biochemical and clinical manifestations of this familial disorder do not appear until after childhood. Parathyroidectomy did not significa reduce the hypersecretion in the patient in who this operation was done first.

8029 CYTOLOGY OF ISLET TUMOURS AND HYPER-PLASIAS ASSOCIATED WITH THE ZOLLINGER ELLISON SYNDROME. (E.) Cavallero, C. (U. Pavi Italy), E. Solcia and R. Sampietro. Gut 8(2): 172-177, 1967.

ourpose of this study of 6 cases was to
rtain a possible role for the argyrophil-
chromatic cell in the histogenesis of islet
tumors which form part of the Zollinger-
son syndrome together with gastric hypersecre-
and multiple recurrent peptic ulcerations.
opears that on properly fixed human islet
ue both argyrophilia with Davenport silver
egnation and toluidine blue metachromasia
characteristic staining reactions for the
rophil-metachromatic cells which are non-
lin nonglucagon-producing; no morphological
tionships appear to exist between the argyro-
cells of these tumors and the argentaffin
s of intestinal carcinoids. On histochemical
nds, it is suggested that both normal and
r argyrophil-metachromatic or argyrophil-
chromatic cells contain acid protein similar
hat in the antropyloric mucosa of the stomach;
ssible relation between this acid protein and
rin may exist.

PURIFICATION AND PARTIAL CHARACTERIZATION OF ENTEROTOXIN C PRODUCED BY
hylococcus aureus STRAIN 137. (E.) Borja,
. (U. Wisconsin, Madison) and M. S. Bergdoll.
hemistry (Wash.) 6(5):1467-1473, 1967.

rotoxin C, produced by Staphylococcus aureus
in 137, was purified by chromatography on a
cellulose column and gel filtration through
adex G-75 and G-50. The purified entero-
n had a high degree of homogeneity, as deter-
ed by electrophoresis and by synthetic boundary
eading; this was confirmed by estimation of
ity by the double-diffusion tube technic.
highly-purified toxin is a simple, colorless
antigenic protein with a sedimentation co-
icient of 3.0 S. Sedimentation and diffusion
surements disclosed a molecular wt. of approx.
000. The basic nature of the protein was
wn by its isoelectric point, which is 8.6 in
onal buffer of 0.1 ionic strength. The toxin
a marked degree of toxicity; 5 μg produced
sis in rhesus monkeys (2-3 kg) within 2-5 hr.
er its intragastric admin. Symptoms of food
soning were noted in 7 of 9 animals that
eived the toxin (0.5 μg/animal) by i.v. inj.
pactness of the enterotoxin molecule was sug-
ted from data on intrinsic viscosity, axial
io and frictional ratio.

31 EXPERIMENTAL ALLERGIC ENTEROCOLITIS.
(Rus.) Nogaller, A. M. (Astrakhan
I. Inst., USSR) and G. A. Trubnikov. Biull.
sp. Biol. Med. 63(2):38-41, 1967.

periments were performed on 25 dogs, of which
were controls (5 received only Freund's
juvant and 5 received intestinal antigen without
e adjuvant). Antigen for immunization was
epared in the following manner: mucous membrane
canine large intestine was washed with sterile
ysiological soln., ground down with quartz
nd, diluted with physiological soln. in the
ratio of 1:1 or 1:2 and centrifuged for 30 min. at 5000 revolutions/min.; the supernatant was removed, merthiolate added and mixed with Freund's adjuvant in the ratio of 1:2. The dogs were immunized s.c. twice (with a 7-day interval) with this mixture of intestinal antigen and Freund's adjuvant (3 ml/admin.), and they were observed for 1-6 mo. Approx. 10 days after the final inj. there was an exacerbation of appetite and vomiting, which included mucus and blood; RBC and WBC appeared in the feces, and there was inflammatory intestinal hypersecretion. The content of enterokinase and alkaline phosphatase in the feces increased 8-10-fold and erosive-catarrhal colitis was evident. A progressive enterocolitis with increasing cachexia in 3 animals resulted in death 1 mo. after admin. of the antigen; in 6 animals enterocolitis disappeared and they were cured after 2-3 mo. In the other 6 dogs acute colitis was less pronounced and they were cured after 1-1.5 mo. No pathological conditions appeared in control animals. The Coomb's and Steffen's reactions were negative during the first wk. after the end of immunization; they were slightly positive by the second wk. and strongly positive after 3 or more wk. Animals which died or were sacrificed at the peak of enterocolitis displayed marked hyperemia of the mucous membrane of the large intestine, the distal part of which had multiple erosions and ulcers. Small intestinal mucous membrane displayed individual sections of hyperemia, edema and hemorrhage and histological examination revealed a pronounced picture of inflammation. In animals sacrificed after 4-6 mo. of observation, and in all controls, there were no signs of inflammation in the large or small intestine. Thus, models of allergic enterocolitis can be made by isoimmunization with large intestine mucous membrane tissue; this can serve as an indirect proof of the autoallergic theory of pathogenesis of nonspecific ulcerative colitis in man.

8032 VIRULENCE AND TOXICITY OF ENTEROPATHOGENIC INTESTINAL BACTERIA IN ADRENALECTOMIZED ANIMALS. (Rus.) Krivonosova, R. T. (Leningrad Med. Inst., USSR). Biull. Eksp. Biol. Med. 63(2):45-46, 1967.

Albino mice (approx. 1000; 1.5-2.0 mo. old; 16-18 g body wt.) were bilaterally adrenalectomized and infected 6 days later with 12 strains of enteropathogenic Escherichia coli $0_{55}:B_5$; some received phagolysate 48 hr., 6 and 12 days after adrenalectomy. The LD_{50} of all strains of bacteria for adrenalectomized mice fluctuated between 5-16 x 10^6 bacteria, while that for controls (not adrenalectomized) ranged between 50-1500 x 10^6 cells. The sensitivity of adrenalectomized mice to infection by these cultures increased from 6-300 fold. The toxicity of all microorganisms of these cultures was similar, but the ability of the bacteria to multiply in the organism varied considerably. Thus, intact animals were more suitable to determine the comparative virulence of the cultures, while adrenalectomized animals were better for demonstrating slight differences in toxicity. For controls, the LD_{50} of enteropathogenic E. coli phagolysate exceeded 1 ml; in adrenalectomized mice the LD_{50} was 0.18 ml 48 hr. postoperatively, 0.22 ml 6 days postoperatively and 0.4 ml 12 days postoperatively. Thus, in order to determine toxicity of phagolysate, the most suitable time for study was 2-6 days after adrenalectomy; however, their increased sensitivity was preserved to almost the same degree at later periods. A similar study using older mice (approx. 2 yr. old; 30-32 g body wt.) yielded similar results. Thus, age had no critical importance in determining the residual toxicity of phagolysates.

8033 LONG-TERM RESULTS OF CHEMOTHERAPY OF OPERABLE CANCER OF THE GASTROINTESTINAL TRACT.

(E.) Blixenkrone-Møller, N. (U. Aarhus, Denmark). Acta Chir. Scand. 133(2):157-159, 1967.

The following drugs were used: chlormethine N-oxide in 2 courses, each of 600-700 mg; cyclophosphamide in 1 course of 4000 mg. During the first 2 yr. of the period of the study (1957-1961), the former drug was used, after that the latter. The subjects were: cancer of the colon, 48 received chemotherapy, 48 did not; cancer of the rectum, 57 with, 87 without; cancer of the stomach, 23 with, 23 without. In the colon group, survivals for those with and without chemotherapy, resp., were: after 5 yr., 65% and 56%; after 8 yr., 61% and 42%. In both groups 70% of the deaths were due to cancer. The differences in survival times between the 2 subgroups were statistically significant. No differences were demonstrable in either the rectum group or stomach group. Studies with a longer regimen of therapy are suggested.

8034 GROWTH HORMONE CONCENTRATION IN TUMOR PATIENTS.

(Rus.) Gazetov, B. M. (All-Union Res. Inst. Clin. Exp. Endocrinol., Moscow) and M. I. Balabolkin. Vop. Onkol. 12(12): 30-34, 1966.

In 40 patients (23 men, 17 women; 30-70 yr. old) with various tumors (located in the stomach in 17, rectum in 11, large intestine and recurrent gastric tumors-3 each, kidneys, 2 each, and 1 each in the pancreas, thyroid gland, liver, ovaries and papilla of Vater), the av. conc. of growth hormone was 31.2 µg%, compared to a level of 17.4 µg% in 35 essentially normal controls. In the tumor patients the level of growth hormone was independent of age, sex, or duration and stage of the disease. No sex differences in the level of the hormone were found among the healthy controls. Growth hormone level was highest in the liver (38.4 µg%) and stomach (35.5 µg%); in the thyroid gland, papilla of Vater, recurrent gastric tumors, large intestine, rectum and kidney it av. 24.7-32.0 µg%, and was lowest in the pancreas and ovaries (20.0 µg%). The highest level of growth hormone was found in mucous and primary liver cancer (38.4 µg%), while it ranged from 26.0 µg%-31.9 µg% in adenocarcinoma, hypernephroid and primary liver cancer and was lowest in squamous cell cancer (18 µg%). In a study of 20 patients, after radical removal of the tumo (i.e., Stages 1 and 2 of the disease) and lymp nodes, the growth hormone level decreased to normal values 2 wk. after surgery; however, af nonradical or palliative surgery (Stages 3 and of the disease), the level of growth hormone i creased, evidently in parallel with tumor deve ment.

8035 DETECTION OF COMMON CANCER ANTIGEN I TUMORS OF DIFFERENT LOCALIZATION AND HISTOLOGICAL STRUCTURE.

(Rus.) Rogalskii, V. (Gertzen State Oncol. Inst., Moscow). Biull. Eksp. Biol. Med. 63(3):110-112, 1967.

The semimicro modification, according to A. I. Gusev and V. S. Tsvetkov, of the agar precipit tion reaction, and monospecific antitumor sera against human large intestinal tumor tissue, o tained by immunization of rabbits with water-s extracts from tumor tissue of 7-8 individuals, were used in this study. Only extracts from tumor cells were used after absorption of immu sera by normal antigens of serum, kidney, sple lung, liver and normal mucous membrane of the large intestine. Specific cancer antigens wer found in 12 of 51 tumors. Tumors containing such an antigen were localized in the stomach, lungs, esophagus and thyroid gland, and histological structure of the tumors included squam cell cancer, adenocarcinoma, solid and microcellular cancer. All of the tumors contained identical cancer antigen. In a study of extra from human embryonal tissues (twelve 6-8-wk.-o embryos), this antigen was not detected, and i is concluded that the antigen is not embryonic It is the author's opinion that this study ver fies the hypothesis that several immunological separated groups of specific tumor antigens ex it is possible that a group of specific antige is related to a group of etiological factors w together cause malignancy.

8036 THE GASTROINTESTINAL TRACT. AN OFTE FORGOTTEN SOURCE OF PROLONGED FEVER.

(E.) Rakatansky, H. (U. Chicago, Ill.) and J. Kirsner. Arch. Intern. Med. (Chicago) 119(4): 321-328, 1967.

Diseases of the gastrointestinal tract may oft have fever as a primary manifestation. Specif infectious agents include Salmonella, the viru of infectious and serum hepatitis, tuberculosi pyogenic bacteria involving the liver, and occasionally the lung as a result of esophageal reflux in achalasia, and, rarely, parasitic in festations. Nonspecific inflammations with fe as a primary feature include cirrhosis of the liver, regional enteritis, and rarely, ulcerat colitis. Neoplasms of the gastrointestinal tr also may manifest initially as obscure fever, especially Hodgkin's disease and tumors of lymphoid tissue. The examination of patients "obscure" fever should include complete uation of the gastrointestinal tract. Analysis he records of 30 unselected patients hospital- at Billings Hospital with a discharge diag- s of fever of unknown origin and all of whom documented fever for at least 1 wk., revealed only 12 had complete X-ray examination of gastrointestinal tract, including examinations he gallbladder, esophagus, stomach, duodenum, n, and in some cases, the small intestine; ad no gastrointestinal examinations, and 6 incomplete studies. Five case histories are n in some detail.

7 ROENTGENOLOGIC STUDIES OF THE ALIMENTARY TRACT IN KWASHIORKOR. (E.)

Kowalski, R. sp. Gabriel Toure Bamako, Republic of Mali). . J. Roentgen. 100(1):100-112, 1967.

in roentgenologic studies of the abdomen were e of 79 African children with various degrees kwashiorkor, ranging from extremely severe different stages of the disease, including trecovery examination (58 children), to in- ient and mild forms (19 cases), and the dry e., non-edematous) form (2 cases). Barium fate roentgenograms were made at 15-, 30-, 45-, 60-min. intervals, and fluoroscopic examina- ns were made of peristalsis. Ba enemas also e used. The presence of fluid levels in the ll intestine was demonstrated. The principal ntgenologic signs of kwashiorkor are based motor function disturbances. Findings were nd to depend on severity and duration of the ease. The 77 severe and mild cases showed ked damage of motor function of the entire mentary tract, especially the propulsive tor but, the ring construction was pronounced. one case, motor function was still impaired yr. after onset of the disease. Impairment found to occur anywhere from the esophagous the colon. Hypertonicity of the entire tract too appreciable to be due to anxiety.

38 USE OF $^{51}CrCl_3$ IN THE DIAGNOSIS OF PROTEIN-LOSING ENTEROPATHY. (E.)

lker-Smith, J. A. (Royal Prince Alfred Hosp., dney, Australia), A. P. Skyring and S. P. stillis. Gut 8(2):166-168, 1967.

llowing i.v. inj. of radioactive chromic chloride saline (100-200 µc, single dose), blood samples re taken at 5 min. and then every second day for days. Total fecal and urinary radioactivity re also measured in 5-day samples. Binding to rum proteins appeared to be virtually instan- neous and was also exceptionally tight. Among control patients without excessive enteric otein loss, 5-day fecal radioactivity ranged om 0.1-1.0% of the total inj. dose (mean = 0.5%). ong 5 of 6 patients with ulcers, it ranged from .8-16.5%; in the sixth, in whom ulcerative lesions re limited to the rectosigmoid region, it was .0%. Among 8 of 9 patients with adult celiac sease, it ranged from 1.2-7.4%, including 5 of 9 with subtotal villous atrophy (range = 1.1-7.4%; mean = 4.1%) and 3 of 9 with partial villous atrophy (range = 1.2-3.0%; mean = 1.83%). Increased fecal radioactivity was also found in 5 other patients, suffering from alcoholism (1.8%), idiopathic hypogammaglobulinemia (1.9%), lymphangiectasia (2.0%), dermatomyositis (4.5%) and melanomatosis of the small intestine (17.5%). Normal-range values (0.5% and 0.7%, resp.) were seen in patients with acute constrictive pericarditis and nephrotic syndrome. There was a statistically significant, direct relationship between the degree of hypoalbuminemia manifested and the amount of stool radioactivity. Levels of urinary radioactivity were substantially the same in the patient and control groups. The mean half-life of the inj. in controls was 9.2 days (range = 5.0-13.7 days); in patients with fecal radioactivity exceeding 1.0%, it was 5.6 days (range = 2.8-9.4 days). It is concluded that the *in vivo* labeling of serum proteins is a simple and effective technic for demonstrating enteric protein loss, although the method does not permit concurrent estimation of the daily turnover of albumin.

8039 SKIN REACTIVITY IN PATIENTS WITH CHRONIC DISEASES OF DIGESTIVE ORGANS. (Rus.)

Burykina, G. N. (Leningrad Sanit.-Hyg. Med. Inst., USSR). Vestn. Derm. Vener. (11):10-15, 1966.

Skin reactivity was studied in 3 groups of patients: Group 1, 31 patients with chronic diseases of the stomach and liver (chronic gastritis and hepatitis of 2-15 yr. duration); Group 2, 28 patients with nonspecific ulcerative colitis; and Group 3, 12 patients with chronic spastic colitis. All of the latter had disturbances of intestinal function and many had chronic gastritis with decreased secretory function of 5 mo.-15 yr. duration. Skin diseases were found in 22 of 71 (pruritus in 10; recurrent urticaria and drug toxicodermia in 4; seborrhea in 4, and other dermatoses in 4). In more than 50% of the patients of Group 2 and in 8 patients of Group 1, skin sensitivity toward electric current was increased, while 14 (mostly with liver cirrhosis) showed a marked decrease in such sensitivity. Sensitivity toward heat and cold was decreased 3-4-fold in nearly all of the patients compared to healthy controls. Skin sensitivity toward cold in the abdominal region was decreased 8-9-fold in Group 2 patients. Sensitivity to pain was also markedly decreased in all of the patients. Differentiated responsive vascular reaction on chemical transmitters of neural impulses to histamine and serotonin were absent in almost all of the patients in Groups 1 and 3, while 15 patients from Group 2 had pronounced spastic reactions to epinephrine which exceeded the normal reaction by 2.3 times. There was increased capillary permeability in 66% of the patients in Group 2 and in 33% of those in Group 1. The functional changes of the vessel were spasmogenic. A repeated study 1.0-1.5 mo. after treatment in 11 patients from Group 2 revealed that skin sensitivity had approached normality; however, the changes of vascular function were more stable. It is suggested that during the examination of patients with dermatoses and institution of general therapy, special attention should be directed to the general condition of the digestive organs, and if possible, intestinal autointoxication should be eliminated.

8040 FUNCTIONAL STATUS OF THE SKIN AND THE DIGESTIVE ORGANS SYSTEM IN THE PATHOGENESIS OF SOME DERMATOSES. (Rus.) Gorbovitskii, S. E. (Leningrad Sanit.-Hyg. Med. Inst., USSR), A. D. Troitskaia, E. I. Arkhangelskaia, G. N. Burykina, G. A. Ustinova and K. Y. Mikhalevskaia. Vestn. Derm. Vener. (11):3-10, 1966.

Pathologic changes of the digestive organs were found in 205 of 256 patients with eczema (103 anacidic, 26 hyperacidic, 71 hypoacidic-gastritis and 3 duodenal ulcer), 33 of 35 patients with epidermophytosis with allergic rash, 50 of 75 patients with erythrodermia and in 60 patients with drug toxicodermia (intestinal dyskinesia, chronic colitis and adhesive disease); such changes were less frequent in 25 patients with psoriasis and 25 patients with lichen ruber planus. Liver detoxification was markedly depressed in 101 patients, and moderately depressed in 85, of 294 patients with eczema, in 55 and 9, resp., of 75 patients with erythrodermia, and in 15 and 16, resp., of 60 patients with drug toxicodermia; 16 of 35 patients with epidermophytosis showed marked depression of this function. Liver carbohydrate function was pathologic in 62 of 104 patients with eczema, in 57 of 65 patients with erythrodermia and 41 of 60 patients with drug toxicodermia. Most of the patients with eczema showed disturbances of the functional condition of the cutaneous receptors and higher neural centers. Sensory chronaxie was prolonged; the vascular reactions of the skin to epinephrine, acetylcholine and histamine were either marked (37%), undifferentiated and distorted (27%) or low (13%), reflex reactions to cold stimuli markedly exceeded in force and duration the reaction to heat, and were more pronounced in patients than in healthy controls, and sensitivity of skin receptors to electric current was increased at the site of lesions and decreased in normal regions. The tactile sensitivity of the skin in areas of lesions was markedly decreased in 90% of the patients and remained unchanged on healthy skin. Sensitivity of the skin to facultative chemical stimuli was markedly increased in 42% of the patients with eczema, and became normalized during recovery. Changes of skin reactivity in patients with epidermophytosis were similar to those observed in eczema patients. Erythrodermia patients showed a strong reaction to epinephrine and none to acetylcholine and histamine. In patients with toxicodermia and erythrodermia, during the acute period, capillary fragility and vascular permeability were increased, and hemodynamic disturbances of a spastic-atonic nature were present; during the period of clinical cure tonus of the blood vessels was normalized in 4 of 60. In patients with psoriasis the sensiti to electric current was increased in the lesion and the perifocal zone, while tactile sensitivi was increased in the perifocal zone and healthy skin and markedly reduced in the lesions; the reaction to epinephrine and histamine was more pronounced in the patients than in the healthy controls. During the period of recovery all persons tested returned to normal. In patients with lichen ruber planus, the rheobase was shortened, sensorial chronaxia was prolonged, tactile sensitivity was decreased and the react to histamine was marked; reaction to acetylchol and epinephrine was the same as in healthy controls. In contrast to patients with eczema and psoriasis, healthy skin in all of the patients with lichen ruber planus exhibited normal physiological indices. In the authors' opinion this relationship between cutaneous disorders and digestive disease is definite and constant.

8041 SJÖGREN'S SYNDROME. ITS ROENTGENOGRA FEATURES. (E.) Silbiger, M. L. (NIH Bethesda, Md.) and C. C. Peterson, Jr. Amer. J Roentgen. 100(3):554-558, 1967.

A review of all available X-rays of 42 patients with confirmed Sjögren's syndrome (40 women, 2 men; aged 25-73; 2 of 40 with concurrent scleroderma, 3 of 40 with reticulum cell sarcom confirmed the presence of concurrent rheumatoid arthritis of the hands and wrists (13 of 36 for whom appropriate films were available), ankles and feet (12 of 36), knee (8 of 36) and shoulde (4 of 17). Comparable tabulations for destruct juxta-articular changes were 5 of 36, 4 of 36, 0 of 36 and 1 of 17, resp.; for osteoarthritis, 1 of 36, 0 of 36, 2 of 36, and 1 of 17, resp. Also found were 1 case each of vascular calcifi tion of the feet and ankles, chondrocalcinosis of the knee. Four of 5 X-rays of the temporomandibular joint showed rheumatoid arthritic changes. Of 37 X-rays of the cervical spine, 9 showed osteoporosis; 8, abnormal atlantoaxial separation; 2, apophyseal joint destruction; 6, osteoarthritis. Of 35 X-rays of the thoracic spine, 18 showed osteoporosis; 5, osteoarthriti Of 35 X-rays of the lumbar spine, 16 showed osteoporosis; 4, osteoarthritis. Of 36 X-rays of the pelvis and sacroiliac, 12 showed osteoporosis; 5, sacroiliitis; 5, rheumatoid arthrit of the hip. Of 42 X-rays of the chest, 14 showe reticular-nodular infiltration; 4, patchy infiltration; 1, hilar lymph node enlargement; 1, bronchiectasis. Ductal and/or alveolar ectasia appeared in 31 of 33; osteoporosis of the skull, in 2 of 17; sinusitis, in 1 of 12; hepato- or splenomegaly, in 7 of 22. Twenty-five X-rays of the upper gastrointestinal tract showed 1 case each of gastric ulcer, duodenal ulcer and reticulum cell sarcoma of the stomach. Lymphadenopathy was found in 3 of 5 patients undergoi lymphography; nephrocalcinosis, secondary to renal tubular acidosis, in 1 of 13 in whom the renal structures were visualized. It is conclu

this disorder represents a complex, general-
systemic disease process in which much
emphasis needs to be placed on destructive
and joint changes, chest infiltration and
ccasional occurrence of abnormal lymphographic
erns and/or nephrocalcinosis.

AUTOPSY INCIDENCE OF DISEASES AMONG
SOUTHWESTERN AMERICAN INDIANS. (E.)
nenbach, D. D. (USPHS Indian Hosp., Phoenix,
). Arch. Path. (Chicago) 84(1):81-86, 1967.

utopsy study of 328 American Indians (78% of
h came from the Pima, Apache and Papago
es) from southwestern tribes, representing
ox. 20% of all southwestern Indian deaths over
yr. period showed that there was no decrease
he incidence of cancer (53 of 328 or 16.2%)
g this group. The gallbladder and biliary
was the most frequent primary site of
gnancy and its incidence (13 cases) was more
6 times that of the general population.
inoma of the stomach, colon and lung fell
w the incidence expected in the general popula-
. The incidence of cholelithiasis among
hwestern Indians (29.9%) in both males and
les was almost twice that of the white popula-
. The prominence of diabetes mellitus (18.3%),
enital malformations, active tuberculosis
%) and portal cirrhosis (12.8%) in these
hwestern Indians suggests that there are
tic, socioeconomic and environmental factors
his population which differ from those of
general population.

ANATOMIC ETIOLOGY AND OPERATIVE TREAT-
MENT OF PEPTIC ESOPHAGITIS: AN
IMENTAL STUDY. (E.) Bombeck, C. T. (U.
ngton Sch. Med., Seattle), T. Aoki and L. M.
. Ann. Surg. 165(5):752-764, 1967.

ost important barrier to gastroesophageal
x is the lower esophageal sphincter, whose
tence may be lost by intrinsic destruction
s musculature or extrinsic distraction of its
by tension directed through the phreno-
ageal ligament. Conventional Allison
r and its modifications are effective in
ing hiatal herniation and in preventing
x due to extrinsic distraction of the
cter, but these measures are inadequate to
nt reflux due to intrinsic failure of the
cter. The only adequate operative procedure
ch cases is one that can support or replace
cter function under conditions of both
nsic failure and extrinsic distraction;
loplasty meets these criteria. The Nissen
plication was tested against experimental
s of reflux (in dogs) due to both causes.
s 100% effective in preventing reflux when
mained intact. Short-term drawbacks of this
dure included inability to vomit in a
ificant number of animals evaluated (5 of 12,
2%), and failure of valvuloplasty in one dog
in 2 mo. of operation due to separation at
suture line. From these studies it is
ested that hiatal hernia, which is due to a
xation of the phrenoesophageal ligament
wing the stomach to slide into the thorax,
acid-peptic reflux, which is due to failure
he lower esophageal sphincter, are 2 separate
distinct entities which may or may not occur
ther. Successful repair of a hernia must be
idered separately from successful alleviation
eflux, and any procedure that maintains
ial reduction while permitting reflux to
inue should be considered a failure.

7 QUANTITATION OF LOWER ESOPHAGEAL
SPHINCTER COMPETENCE. (E.) Winans,
. (U. Hosp., Boston, Mass.) and L. D. Harris.
roenterology 52(5):773-778, 1967.

ients were divided in 2 groups: Group 1, 14
mals (21-81 yr., av. 30) upon whom 80 measure-
ts of lower esophageal sphincter pressure
e made; Group 2, 7 patients, with grossly
mpetent sphincters as indicated by free
troesophageal reflux of Ba (24-86 yr., av. 50,
selected for absence of hiatal hernia), on
m 33 measurements were made. Pressures were
nsmitted by water-filled polyvinyl tubes
ternal diameter 1.4 mm). One tube was
nected directly to a transducer and was
ical of systems used in previous studies of
s sphincter (A). The other system (B) was
ified by placing between tube and transducer
idearm through which water was continually
used by a pump at 6-8 μliter/sec. Each tube
had a 1.2 mm lateral recording orifice, and the tubes were assembled so that pressures were recorded at points 5 cm apart. All manometric studies were performed with subjects supine. Belt pneumographs around the chest and larynx monitored respiration and swallowing, resp. Pressures were recorded as assembly was withdrawn by 1-cm increments from stomach to esophagus. Pressures obtained with the conventional system (A) could not differentiate between Groups 1 and 2; pressures recorded by System B from the same sphincters allowed a clear separation between Groups 1 and 2. Reproducibility of max. sphincter pressure in System B was evaluated by serial measurements from the same normal subject on 50 occasions over 6 mo. Although these pressures varied over a range of 20-35 mm Hg, they were in every instance clearly higher than pressure recorded by the same method from an incompetent sphincter. It is suggested that the failure of the conventional method was due to sealing of the recording orifice by the sphincter; this was eliminated by constant infusion of water.

8118 TRANSITION FROM SYMPTOMATIC DIFFUSE SPASM TO CARDIOSPASM. (E.) Kramer, P. (Boston U. Med. Ctr., Mass.), L. D. Harris and R. M. Donaldson, Jr. Gut 8(2):115-119, 1967.

A patient, 70 yr. old, presented with clinical symptoms of dysphagia, odynophagia, and lower retrosternal pain which worsened progressively over a period of 8 yr. The esophageal radiographic findings after a Ba swallow showed localized, segmental contractions, minimal dilatation and slight emptying; balloon-kymography and response to methachoeine were of little value in differential diagnosis; the manometric records were consistent with the diagnosis of diffuse spasm. The patient's clinical picture changed to one of cardiospasm 8 yr. after the first symptoms of diffuse spasm were experienced, as it appears from clinical and laboratory findings: substernal pressure on eating, relieved by washing his food through with water, and regurgitation. Esophageal radiographic findings showed an absence of peristalsis on swallowing, presence of a narrowed tapered area. Excellent relief symptoms were achieved by a forceful dilatation. Balloon-kymography and manometry also supported the diagnosis of cardiospasm.

8119 THE SIGNIFICANCE OF AN INTRA-ABDOMINAL SEGMENT OF CANINE ESOPHAGUS AS A COMPETENT ANTIREFLUX MECHANISM. (E.) Sicular, A. (Mt. Sinai Hosp., New York, N. Y.), B. Cohen, A. Zimmerman and A. E. Kark. Surgery 61(5): 784-790, 1967.

A sufficiently long segment of intra-abdominal esophagus functions as a competent barrier to reflux of gastric contents into the esophagus, the result of the forces exerted by intra-abdominal pressure on the collapsible subdiaphragmatic esophageal segment. This was determined by studies of the esophagus and the esophagogastric junction in the unanesthesized dog by means of observations on Ba swallow, by cineradiography and intraluminal pressure. As a result of these studies it is indicated that, clinically, when reflux occurs as a result of hiatus hernia and where manometric studies show poor or absent sphincter function, surgical construction of an infradiaphragmatic segment of esophagus of sufficient length would appear to be necessary for adequate restoration of normal function.

8120 CORRELATION OF ELECTRIC SURFACE POTENTIALS, INTRALUMINAL PRESSURES, AND NATURE OF TISSUE IN THE GASTROESOPHAGEAL JUNCTION OF MAN.

(E.) Meckeler, K. J. H. (Boston U. Sch. Med., Mass.) and F. J. Ingelfinger. Gastroenterology 52(6):966-971, 1967.

Since intraluminal gastric potential is usually negative with respect to skin, and esophageal potential positive, the site of max. potential change, determined on withdrawing an electrode from the stomach to the esophagus, has been used to identify the gastroesophageal mucosal junction. In order to ascertain if this practice is valid in man, simultaneous mucosal biopsies were taken proximal and just distal to the point where max. change in potential difference was recorded on withdrawing an electrode from stomach to esophagus. Simultaneous measurements of intraluminal gastroesophageal pressures were carried out. The test subjects included 15 men and 7 women, 34-77 yr. old, all of whom were capable of secreting gastric juice with a pH of less than 3.5. Fourteen had no known gastrointestinal disorders, 5 had peptic ulcer disease, 1 had a partial gastrectomy without vagotomy and 2 had hiatal hernia. In 18 of 22 subjects in whom a clearly defined change in potential difference could be recorded, the end point of max. potential difference change correlated 12 times with the presence of stratified squamous epithelium, and 6 times with junctional columnar epithelium devoid of parietal cells. From the other biopsy site, 25 mm distal, gastric mucosa with parietal cells was consistently obtained. Changes in potential difference began shortly before, or coincident with, the junctional zone of increased intraluminal pressure, whenever this could be identified. Changes in potential difference appeared to correlate better with the presence or absence of parietal cells than with the actual junction of columnar gastric and squamous esophageal epithelium. However, since parietal cell-containing gastric epithelium and squamous epithelium were not widely separated in most cases, changes in potential difference identified the location of the mucosal gastroesophageal junction accurately in 2 of 3 cases.

8121 BENIGN STRICTURE OF THE ESOPHAGUS SECONDARY TO GASTROESOPHAGEAL REFLUX.

(E.) Paulson, D. L. (Baylor U. Med. Ctr., Dallas, Tex.). Ann. Surg. 165(5):765-779, 196

A report is presented of 56 patients (approx. equal sex incidence; 4-84 yr. old) with benign stricture of the esophagus secondary to gastro esophageal reflux; 26 were longitudinal stenoses and 30 annular strictures. Of those with longitudinal stenosis, 70% were older tha 60 and 30% older than 70; patients with annula strictures were younger, only 30% being older than 60 and 15% beyond age 70. A previous history of gastroesophageal reflux, heartburn, regurgitation, substernal pain and suprasterna discomfort with choking was obtained from all patients with longitudinal or ascending stenos and from 27 of 30 with annular strictures. Diagnosis of esophageal stricture was made by radiological studies of the esophagus, includi cinefluorography. Treatment in all 26 patient with longitudinal stenosis consisted of transthoracic gastrotomy, retrograde dilatation and repair of the hiatal hernia in 11; resection a colon interposition, vagotomy and pyloroplasty in 10; cardiomyotomy, esophagoplasty and repai of the hiatal hernia in 2; endoscopic dilatati only in 2; and gastrostomy only in 1. Of 30 with annular strictures, 21 were treated by transthoracic gastrotomy, resection of the stricture at the submucosal level, suture of t mucosa and repair of the associated hiatal hernia; 5 had gastrotomy, dilatation and herni repair, 1 endoscopic dilatation and hernia rep 2 endoscopic removal of the foreign body only, and no operation in the remaining patient. There was 1 death in 55 patients. Results of surgery for annular strictures in 26 treated b either excision or dilatation with repair of t hiatal hernia were satisfactory if an adequate lumen was provided and gastroesophageal reflux corrected; dysphagia and symptoms of significa reflux were relieved in 18 of 23 patients followed for periods of up to 5 yr. Objective postoperative cinefluography of the esophagus 19 patients showed no reflux in 14 (75%) and, reflux in 5. Results of gastrotomy, dilatatio and repair of hernias for longitudinal stensos in 11 patients were immediately satisfactory, but repeated postoperative endoscopic dilatations were necessary in several. In 10 patients in whom resection, colon interpositio vagotomy and pyloroplasty were done, there was satisfactory relief from dysphagia; however, there were a few disturbances in motility and passage of food through the interposed colon. One patient had late bleeding, apparently from ulceration at the cologastric junction. It is concluded that benign strictures of the esophagus of either the ascending or annular types arise as a result of reflux esophagitis, culminating in chronic inflammation, ulceratio of the mucosa and submucosal fibrosis.

8122 SURGICAL CONSIDERATIONS IN THE MANAGEMENT OF ACHALASIA OF THE ESOPHAGUS.

(E.) Sawyers, J. L. (Vanderbilt U. Sch. Med.,

ville, Tenn.) and J. H. Foster. Ann. Surg.
5):780-785, 1967.

tal of 73 patients (19-85 yr. old; av. age
were treated for achalasia of the esophagus.
hagia had been present in 97% of the patients;
complained of regurgitation and wt. loss was
ificant in 67% (av. wt. loss was 29 pounds,
1 patient had lost 94 pounds). Pain was an
equent initial symptom, occurring in only 13
ents (18%). The av. duration of symptoms was
yr. before initiation of treatment.
hageal dilatation was performed in 64
ents; 21 (33%) were failures and required
equent surgical procedures; 44% had a good
lt from dilatation, 11% had fair results and
had poor results. Included in the latter or
hose requiring operation were 6 patients who
ained perforations of the esophagus during
tation; 2 of 6 died as a result of perforation,
mortality for the treatment of achalasia by
tation. Thirty patients had operations for
lasia; 22 had a modified Heller procedure,
8 were treated with other procedures (1
licz retrograde dilatation, 5 Wendel cardio-
ty and 2 Heyrovsky esophagogastrostomy.
lts of the modified Heller procedure were
in almost 80% of the patients, and there
no operative mortality. Of those with other
edures, 4 (50%) developed esophagitis, and
d good results. Of 5 (21%) with poor results
the modified Heller procedure, all 5 had
rgitative esophagitis, 4 required reoperation
3 had dilatations. Contributing factors to
atisfactory results after the modified Heller
cedure included technical errors, development
postoperative hiatal hernia and partial gas-
outlet obstruction leading to reflux
phagitis. It is concluded that the modified
ler procedure (esophagocardiomyotomy) is
ective and deserves wider application as
tial treatment for selected patients with
alasia.

3 EXPERIENCES WITH THE TREATMENT OF 59 PATIENTS WITH LOWER ESOPHAGEAL WEB.

) Postlethwait, R. W. (Duke U. Med. Ctr.,
ham, N. C.) and W. C. Sealy. Ann. Surg.
(5):786-796, 1967.

tal of 59 patients (52 men, 7 women; 37-78
old) were treated for lower esophageal web
hatzki's ring). Episodic aphagia was the
t prominent symptom in 38, while progressive
ficulty in swallowing was present in 14; 7
no dysphagia. Symptoms of reflux were pre-
t in 19, although only 6 had slight and 2
erate esophagitis by esophagoscopy (the latter
done on 43, and the web identified in 18).
tal hernia repair and partial excision of the
was done on 15 patients. Five had no
urrence of hernia or web, and remained
mptomatic; 5 had a recurrent web but were
l, while 5 also had recurrence of the web
h associated difficulties. Seven patients
hiatal hernia repair and digital dilatation
of the web; 2 were asymptomatic with no recurrence, while 2 had recurrence of both web and hernia, with symptoms of reflux. Hiatal hernia repair only was performed on 14; 3 who had reflux were relieved and 3 who had episodic aphagia were improved. Two who had mild dysphagia had no further difficulty in swallowing but experienced occasional heartburn. Postoperative dilatations were necessary in 4 and another refused dilatation. One was operated upon for symptoms of marked reflux. In those who had satisfactory radiographs during follow-up studies, the web was present in 6 and was not visualized in 3. Dilatation of the esophageal web was done on 11 patients; in 9 there was no subsequent dysphagia. Twelve patients were managed by diet alone (eating slowly, taking small bites and chewing food thoroughly); 6 were asymptomatic, 1 takes liquids only, and 1 was considered to have done well on the diet (this patient subsequently died of myocardial infarction), while 1 had dysphagia if tense, 1 experienced occasional dysphagia and 1 had complications in swallowing a meat bolus. It is concluded that the most conservative management consistent with good results appears to be indicated in the management of the lower esophageal web.

8124 RESECTION OF SQUAMOUS-CELL CARCINOMA OF THE OESOPHAGUS WITH END-TO-END OESOPHAGEAL ANASTOMOSIS.

(E.) Davidson, J. S. (Roy. Infirm., Bradford, England). Brit. J. Surg. 54(1):63-70, 1967.

Case reports are given of 10 resections of squamous cell carcinoma of the esophagus with direct anastomosis. One patient with an inoperable tumor died from disruption of the anastomosis. Four had good results: 1 with a carcinoma of the junction of the middle and lower thirds of the esophagus is alive and free from symptoms after 9 yr.; 1 with a carcinoma in the upper third is alive and well after 6.5 yr.; the other 2 died at 80 and 90 yr., resp., the former living in good health for 6 yr. In 5 the results of surgery were poor, with survival of 5 mo. - 2 yr., 7 mo.; in 3 there was histological evidence of inadequate excision; of these, 1 died after a yr., without recurrence in the esophagus, 1 had early local recurrence successfully treated with radiotherapy, and 1, who also had postoperative radiotherapy, did not develop recurrence; recurrence at the anastomosis was not observed in the other 2, although in neither was growth found at the ends of the resected specimens. Criteria for the selection of cases were that the lesion should be seen as a smooth, hard structure less than 5 cm in length. Of 9 who left the hospital, significant dysphagia occurred in 4. Failure to excise an adequate length of esophagus was the main cause of recurrence in this and a longer series. The disadvantages of this procedure (limited applicability; only small excision; high incidence of postoperative dysphagia) are contrasted with its advantages (short procedure; useful in the elderly and ill; patient left with normal alimentary tract and excellent nutrition; no anemia, esophagitis, or sequelae from derangement of Ca metabolism).

8125 RESECTION OF CARDIO-ESOPHAGEAL CARCINOMA. FACTORS CONTRIBUTING TO ITS MORTALITY, PALLIATION, AND CURE. (E.) Magill, T. G. (Columbia-Presbyterian Med. Ctr., N. Y.) and R. L. Simmons. Arch. Surg. (Chicago) 94(6): 865-870, 1967.

Factors which contributed to the operative mortality, palliation and cure rates obtained in 109 cases of esophagogastric resection for carcinoma of the esophagogastric junction were studied over a 20-yr. period, with 98% follow-up. Total operative mortality was 11.9%, which was significantly less than that obtained before 1950 (41%). Patients were considered to have received successful palliative treatment if they survived more than 6 mo. with good deglutition; of all patients, 61.5% were palliated by the procedure. The 5-yr. clinical cure rate for the operative procedure was 7.7% and 9.3% for esophageal and gastric lesions, resp. Operative mortality for the esophageal patients was confined to the 60-69 age range; the stomach group had essentially equal rates for all ages. Two of the three 5-yr. survivors of esophageal lesions were in the 40-49 age group, while 4 of the 5 cures obtained for the stomach were in patients below 60 yr. old. Sixteen of 75 cases (21.3%) of the stomach were in the youngest age group, while only 2 of 34 (6%) esophageal lesions were resected at this age. There were 23 (21.1%) cases of leakage at the proximal suture line in this series; of the 23 patients, 13 (56.5%) died within a 3-mo. period after operation. In 13 early postoperative deaths, 7 were due to leakage at the proximal suture line. Increasing age, extensive spread of the local disease and proximal anastomotic suture line involvement were correlated with poor palliative and curative results. The type of anastomosis and pathology of the lesion could not be correlated with palliative or curative results.

8126 CONCERNING THE BLOOD SUPPLY TO THE TRANSPLANTS USED FOR TOTAL ESOPHAGOPLASTY. (Rus.) Filin, V. I. (Milit. Med. Acad., Leningrad, USSR), A. I. Reshetov and V. F. Zhupan. Vestn. Khir. Grekov. 98(1):32-36, 1967.

A partial necrosis of the large intestine developed in 9 of 40 patients during plastic surgery for lesions of the cervical part of the esophagus and pharynx. There were primary and secondary disturbances in the blood supply of the transplanted organ. Special anatomic and clinical studies revealed that extraorganic vascular bonds were worse in transplants forme from small intestine and stomach, and better i those developed from large intestine. Not all arteries of the small intestine began from the upper mesenteric artery independently; some began from the general stem, giving 2-4 intestinal arteries (in 23 of 40 preparations). In several cases, the upper mesenteric vein and artery had a different number of rami, i.e., 15 of 40 preparations, the number of intestina veins was less than the total amount of intestinal arteries, exhibiting a difference o 1 in 10 of 15 cases, 2 in 4 of 15 cases and 3 1 of 15. In 31 preparations, several intestin veins (2-5) united with the general stem and then flowed into the upper mesenteric vein. In 45 preparations, an anastomosis between the right and left gastro-omental arteries was satisfactory in 19, poor in 10 and absent in 1 It was also found that extraorganic vascular connections were not equally pronounced for different parts of the large intestine, i.e., good, pronounced connections in the right half of the large intestine were found in 19 of 30 preparations, and in the left half of the larg intestine, in 25 of 30 preparations. These findings were demonstrated clinically. Thus, a transplant formed from the left half of the large intestine is better for feeding conditio than that from the right half; an artificial esophagus could almost always be formed from the large intestine. In 26 of 30 preparations of the large intestine, the number and pattern of basic venous stems correlated with the numb and pattern of similar veins. Of some significance during the formation of the trans plant from the small or large intestine was th lack of correlation of the level of the primar division of the basic large intestinal arterie and the level of the input of main rami in similar basic intestinal veins. Such inconsistencies were most frequently found in the right half of the large intestine and occurred more frequently with the ileocolic artery (in third of the cadavers) than with the right and central colic arteries (one-seventh of the cadavers). Intraorgan vascular anastomoses we more pronounced in the gastric transplants and somewhat poorer in those of the large or small intestine. In 32 human cadavers, there was sufficient intraorgan arterial and venous anastomoses in various parts of the small and large intestine for a length of 5-7 cm; this was clinically verified. Venous intraorgan anastomoses of the stomach were more often inadequate than arterial anastomoses. Therefore, in feeding through a transplant, intra- and extraorganic vascular connections are important. Secondary vascular disturbances developed after packing of the transplant in t s.c. or intrathoracic bed; they were provoked by pressing, bending, pulling and twisting, thrombosis or emobili or of the intra- and extraorganic vessels, etc.

7 VAGOTOMY AND PYLOROPLASTY IN THE
MANAGEMENT OF HIATAL HERNIA. (E.)
sant, J. H., R. L. Payne, Jr. and R. E.
lpine. Ann. Surg. 165(6):888-893, 1967.

ty patients (28 women, 22 men; 28-76 yr. old;
were over 40 yr. old) with hiatal hernias
ra-esophageal hernias in 5 patients, sliding
nias in 45) were evaluated and operated upon;
her vagotomy and pyloroplasty or hemogastrectomy
e combined with repair of hernias in 37
ients. The most frequent major presenting
plaints were heartburn (78%) and obstruction
%); others included acute gastrointestinal
orrhage (16%), chronic anemia (16%), pain
%), nausea or vomiting (36%) and excessive
ching (92%). Uncontrolled reflux esophagitis
cases or 48%) was the major indication for
ration. Free HCl, measured in 35 patients
h sliding hernias, was above 20 mEq/liter in
and more than 40 mEq/liter in 15.
ophagoscopy, performed on 34 patients, proved
t useful in evaluating patients with sliding
tal hernias; 30 of 34 patients who were
ophagoscoped had visual evidence of esophagitis.
those with sliding hernias, 21 had upper
ominal lesions; 7 had gallbladder disease and
had either duodenal or gastric ulcers.
gical treatment of hiatal hernia included
ominal repair of sliding hernia plus vagotomy
37 (74%), abdominal repair of sliding hernia
3 (6%), thoracic repair of para-esophageal
nia in 5 (10%), thoracic repair of sliding
nia in 3 (6%) and esophageal resection in 2
). There were no deaths. Six patients
eloped postoperative complications; wound
ections in 5 and thrombophlebitis in 1. Long-
m complications after vagotomy and pyloro-
sty in 35 patients with a sliding hernia
of whom were followed for more than a yr.)
luded diarrhea, bloating and cramps in 10
%), nausea and vomiting in 5 (14%) and the
ping syndrome in 1 (3%). No patient in whom
otomy was performed developed symptoms of
urrent hiatal hernia, although 1 of 18 who
follow-up X-ray studies had anatomic
urrence.

8165 ALTERATIONS IN MUSCULAR AND ELECTRICAL ACTIVITY OF THE STOMACH FOLLOWING VAGOTOMY. (E.) Nelsen, T. S. (Stanford U. Sch. Med., Palo Alto, Calif.), E. H. Eigenbrodt, L. A. Keoshian, C. Bunker and L. Johnson. Arch. Surg. (Chicago) 94(6):821-835, 1967.

Mongrel dogs (12) were laparotomized, and 6 of them each instrumented with 2 or 3 strain gauge type transducers and 3-5 stainless steel electrodes; the strain gauge transducers were placed so that the orientation of the sensitive element was parallel to the underlying circular muscle. The upper gauge was placed on the body of the stomach, the middle gauge on the midantrum and the lower gauge on the pyloric ring when a pyloric transducer was used. After healing of the operative wound, each animal underwent at least 2 insulin and feeding tests in addition to the recording of fasting activity before vagotomy was performed. Bilateral truncal vagotomy was performed in 10 animals, and selective vagotomy in 2. Responses to food and insulin were usually recorded for 2.5-4.0 hr.; feeding tests were limited to 250 g or less of proprietary dog food in order to avoid overdistention of the stomach and alteration of the transducer-gastric wall geometric relationship. Insulin tests were performed by a single i.v. inj. of sufficient regular insulin to reduce the blood glucose to 50 mg/100 ml (usually 12-15 U). These experiments were designed to characterize the motor and electrical disturbances created in the stomach by vagotomy. After vagotomy there was a lowering of mean gastric mechanical electrical rate and a great increase in rate variation and complexity of propagation paths (desynchronization), and an alteration of the character of fasting motor activity (diminution of phasic activity, relative accentuation of tonic activity and desynchronization). Vagotomy also produced a diminution in amplitude and duration of the motor response to food and pyloric opening for a greater percentage of the time than the normal. Selective vagotomy produced no discernible difference in rate change or work function from bilateral truncal vagotomy. Application of these findings to understanding of the clinical problem of postvagotomy motor disturbances is discussed in detail.

8166 MOTOR AND SECRETORY FUNCTION OF THE STOMACH IN DISEASES OF THE GALLBLADDER AND BILE DUCTS. (Pol.) Jasieński, S. (3rd Surg. Clin., Cracow, Poland). Folia Med. Cracov. 8(4):533-627, 1966.

Gastric function was assessed in patients with gallbladder and bile duct disease, and results were compared with those from healthy individuals. Movements of the gastric walls were recorded by measurement of intragastric pressure. There were distinct changes in the appearance of gastograms in patients with biliary tract disease; waves were irregular, of various shape and character, and had an increased amplitude. Disorders in gastric motor function were proportional to the disease state in the gallbladder and its surroundings. The changes were not specific for any particular disease, being an expression of the lesions in the course of inflammation and their influence on other parts of the body, especially in the region of the infectious focus Gastric motor malfunction occurred in other diseases, such as gastrointestinal neuroses an gallbladder cancer; disorders persisted even after surgical removal of the gallbladder. In all of the diseases studied, gastric evacuatio of the Ba meal was markedly delayed compared w healthy normals; this was due to ineffective hyperperistalsis and reflex pylorospasm. Secr tion was assessed on the basis of fractionated portions of gastric juice after admin. of histamine. Dual analysis of the free and boun HCl and pH showed that pathologic processes in the gallbladder caused disorders of gastric acidity. The primary disease is presumably ac companied by gastritis, which may be either hy acidic or hypoacidic. In protracted disease, progressive anatomic changes in the stomach an gallbladder, and advancing age of the patients led to hypoacidic or achlorhydric gastritis. In patients with cholecystitis and cholelithia the efficiency of conc. and excretion of Cl, b free and bound, Na and K were distinctly distu In advanced stages, disorders in values of Na and Cl became more pronounced, but K levels we not distinctly affected. Pepsin levels were higher in the course of cholecystitis, especia in advanced cases, than in healthy persons. Levels of pepsin in gastric juice appeared to inversely proportional to acidity. Gastrochro copy showed markedly impaired excretion of the dye through the gastric mucosa in advanced dis of long duration in older patients; this signi further disturbance of secretory function. Inflammation and other uncomplicated pathologic processes in the gallbladder and bile ducts ha little, or no, effect on the level of total serum proteins. However, the total protein wa markedly increased in the gastric juice of pat especially in advanced disease of long duratio in older patients. Rise in γ-globulins was undoubtedly pathologic and resulted from excessi production of mucus and insufficiency of the gastric glands. Immunoelectrophoresis yielded much smaller quantity of protein fractions in the gastric juice than in serum, especially in advanced inflammatory changes in the gallblad

8167 GASTRIC EMPTYING AND PROPULSIVE INTESTINAL MOTILITY FOLLOWING PARTIAL GASTRIC RESECTION, GASTROENTEROANASTOMOSIS, A ABDOMINAL "TRUNK" VAGOTOMY IN THE RAT. (E.) Nylander, G. (Hosp. Acad., Uppsala, Sweden) a S. Wilkström. Acta Chir. Scand. 133(1):41-54, 1967.

Gastric emptying and propulsive intestinal motility were studied in 290 white laboratory rats divided into an intact control group and perimental groups; the latter consisted of th having the following procedures: Group 1, pa

ric resection with gastroduodenal anastomosis;
ıp 2, partial gastric resection with gastro-
inal anastomosis; Group 3, partial gastric
ction with gastrojejunal anastomosis with
eroanastomosis between the afferent and ef-
ent jejunal loop; Group 4, gastrojejunal
stomosis, excised pylorus, but otherwise intact
nach; Group 5, abdominal "trunk" vagotomy with-
pyloroplasty; and Group 6, abdominal "trunk"
otomy with pyloroplasty. The methods of
ysis comprised direct and indirect measure-
of the quantitative distribution in the
rointestinal tract of $Na_2{}^{51}CrO_4$ at different
ervals after its deposition in the stomach
0 min.). Gastric emptying followed an ex-
ential course in intact controls. In Groups
d 2, gastric emptying showed a more marked
asic course. During the first 15-min. period
emptying was faster than normal, and during
second period it was wholly arrested. Rats
roup 1 had a somewhat faster emptying time.
roup 3, the same proportion of gastric dose
evacuated during the first 15-min. period as
controls. The enteroanastomosis had a retard-
effect on the initially rapid emptying of
gastrojejunostomy. In Group 4, emptying was
er than normal and almost unchanged during
two 15-min. periods. The emptying curve
ered from normal and was more linear. There
retarded gastric emptying in Group 5. The
ying curve agreed in principle with the normal,
initially rapid and subsequently slower course.
roup 6, gastric emptying was quantitatively
al after 30 min.; the effect of vagal denerva-
was eliminated by pyloroplasty. The quanti-
ve distribution in the small intestine of
evacuated portion was expressed as its per-
ile presence in the proximal half of the
l intestine, being given as a function of the
erimental period. Normally, this function was
he same character as that of gastric emptying.
or activity of gastric emptying and the pro-
ive motility of the small intestine were in-
ately correlated in the intact rat. The same
ationship was noted in Groups 1 and 2. The
ially accelerated and subsequently arrested
ric emptying was reflected by initially
id and later discontinued distal distribution
he evacuated portion. The initially acceler-
emptying of the gastric remnant was thought
ave been of essentially hydrostatic deriva-
; the arrested evacuation was attributed to
uction in the contents and mural tension in
gastric remnant in combination with the
ative resistance to continued passive outflow
stituted by the proximal situation of the
cuated portion. The normal extent of gastric
tying in Group 3 after 15 min. was reflected
extreme proximal distribution of the evacuated
tion. Agreement between the course of gastric
tying and the intestinal distribution of the
cuated portion was also noted in Group 4;
courses were linear. This agreement was not
erved in Group 5; the initially faster course
the emptying curve was not reflected by any
distal conc. of the evacuated portion. In
up 6 gastric emptying was roughly normal after
30 min.; at this juncture the pattern of distribution was identical to that in the intact controls. Since both gastric emptying and the distribution in the small intestine of the evacuated portion were normalized after pyloroplasty, vagotomy was regarded as affecting chiefly the function of the pylorus.

8168 GASTRIC FUNCTION IN PATIENTS WITH GASTRIC CARCINOMA. (E.) Shearman, D. J. C. (Roy. Infirm., Edinburgh), N. D. C. Finlayson and R. Wilson. Lancet 1(7486):343-346, 1967.

Gastric acid and intrinsic factor output was studied in 22 patients (13 men, 9 women) with gastric cancer; controls included 11 cases of gastric ulcer (7 men, 4 women), 9 cases of duodenal ulcer (7 men, 2 women) and 10 patients without gastric disorder (7 men, 3 women). The mean output of acid in gastric carcinoma patients was 4.9 mEq (range 0-33.48 mEq); in those with gastric ulcer it was 14.4 mEq (range 3.41-34.41 mEq); in those without gastric disorder and in persons with duodenal ulcer it was 18.7 mEq (range 9.0-39.0 mEq) and 33.1 mEq (range 10.8-66.0 mEq), resp. The difference between the first two groups was statistically significant. Mean intrinsic-factor output for gastric carcinoma patients was 3230 ng U (range 4444-9022 ng U), and for gastric ulcer patients it was 12,840 ng U (range 6026-23,097 ng U); this difference also was statistically significant. In those without gastric disorder and in persons with duodenal ulcer the mean intrinsic-factor output was 14,800 ng U (range 6000-31,800 ng U) and 22,954 (range 10,900-32,900 ng U), resp. No patient with intrinsic-factor antibody was found, but the 2 patients with parietal-cell antibody were achlorhydric and also had the lowest intrinsic-factor outputs. There was no correlation between the extent of gastric mucosal involvement by neoplasm and the results of gastric secretory tests. With regard to tumor site, those patients with higher acid and intrinsic-factor secretion tended to have antral or pyloric tumors, but this division was not absolute. These findings confirm the high incidence of hypo- and anacidity, in addition to a significant depression of intrinsic-factor secretion, in gastric carcinoma.

8169 REACTIVE AND NONREACTIVE ALUMINUM HYDROXIDE GELS. DOSE-RESPONSE RELATIONSHIPS IN VIVO. (E.) Littman, A. (U. Illinois, Chicago). Gastroenterology 52(6):948-951, 1967.

Five aluminum hydroxide gels were prepared with greatly differing solubility in dilute acid; aqueous soln. of aluminum chloride were reacted with sodium carbonate for the reactive types and with ammonia for the nonreactive types. The "acid-consuming capacity" for each gel was determined by the United States Pharmacopeia XV method, in which a weighed amount of gel is shaken for 1 hr. with an excess of 0.1 N HCl at 37°C; the excess acid is titrated with 0.1 N NaOH, using bromophenol blue as the indicator. The composition and properties of each gel was as follows: 1) reactive type, 4.65% Al_2O_3 (wt./wt.), 1.29 ml of gel containing 60 mg Al_2O_3 and 140.5 ml acid-consuming capacity; 2) reactive plus nonreactive, 3.95%, 1.52 ml and 100.8; 3) reactive, 1.74%, 3.37 ml and 61.1; 4) nonreactive, 3.19%, 1.88 ml and 37.0; and 5) nonreactive 1.62%, 3.64 ml and 6.3. The duration of "neutralization" produced by these gels in doses ranging from 7.5-60.0 ml was tested in male patients with basal hypersecretion. *In vivo* results corresponded in general with those obtained *in vitro*. For the more reactive gels (1 and 2), the duration of neutralization increased linearly with logarithm of dose. A 30-ml dose of the more reactive gels produced a pH above 3 lasting 15 min. or more in 90% of the subjects, 30 min. or more in 60%, and 45 min. or more in 30%. Duration of effect was not related to basal secretory rate, except for 7.5 ml doses. For nonreactive gels, increasing the dose had little effect in producing a pH of 3 or more, as based on the criterion of effect for 30 min. or longer. Effectiveness of the gels corresponded to the numerical order described earlier. Reactive (acid-soluble) gels were more effective than insoluble or nonreactive gels. For reactive gels the major factor limiting the duration of neutralization appeared to be gastric emptying.

8170 EXPLORATORY GASTROTOMY IN MANAGEMENT OF MASSIVE UPPER GASTROINTESTINAL HEMORRHAGE. (E.) Freeark, R. J. (Northwestern U. Sch. Med., Chicago, Ill.), W. J. Norcross and R. J. Baker. *Arch. Surg. (Chicago)* 94(5): 684-695, 1967.

Exploratory (long) gastrotomy was performed on 77 patients who required surgery for the control of massive upper gastrointestinal bleeding of undetermined origin. The patients were divided into 2 groups according to the presence or abscence of an abnormality noted at the time of laparotomy and before gastrotomy. Group 1 included 47 patients without any findings at the time of laparotomy to suggest the site of bleeding, and in whom exploration of the widely opened stomach was performed in order to establish the cause. Among the lesions encountered in this series were gastric ulcer in 15, Mallory-Weiss syndrome in 11, duodenal ulcer in 8, diffuse mucosal hemorrhage in 5, ruptured sclerotic vessel in 3, duodenal reduplication and pseudoxanthoma elasticum in 1 each, and the bleeding site was not identified in 3. Group 2 included 30 patients in whom some abnormality was noted before gastrotomy, but gastrotomy was performed because of the uncertainty concerning the relationship of the abnormality to the cause of bleeding. This series included liver cirrhosis in 12, subserosal hemorrhage in 5, perigastric mass in 7, and splenomegaly and postgastrectomy bleeding in 3 each. A significant number of the bleeding sources identified could not have been controlled by empiric resection of the distal two-thirds of the stomach. These results suggest that a properly performed exploratory gastrotomy is a
reliable method of identifying the source of
hemorrhage, and provides access for the defini
treatment of a significant number of otherwise
obscure esophageal, gastric and duodenal lesio

8171 ISOLATION OF THE AUTOANTIGENS RESPON
FOR AUTOANTIBODY FORMATION IN SEIZUR
OF GASTRIC CANCER. (Fr.) Karitzky, D. (Cance
Sci. Res. Inst., Villejuif, France) and P. Bur
Europ. J. Biochem. 1(4):411-418, 1967.

The antigen which produces autoantibodies to g
tric carcinoma was isolated from normal and
cancerous gastric mucosa. The active products
were found to be soluble in both perchloric an
phytic acids, and to be precipitated by ammoni
sulfate. After chromatography on DEAE-cellulo
graphs of the normal and cancerous extracts we
found to be similar. The activity of the auto
antigen was found mainly in the first, and to
lesser degree, in the third of 7 peaks (P_1, P_3
P_1 was subjected to Sephadex G 100 filtration,
after which 3 peaks were usually seen: A, B a
C. Slight differences were observed within th
peaks: C was lower after passage of the tumor
extract than after that of normal extracts.
Antigenic activity was seen only in some tubes
of peak C; 10 µg of isolated peak C material,
from a fraction of phytic acid-extracted cance
mucosa, were sufficient to absorb all antibodi
of the patient's sera. After migration in acr
amide agarose this product displayed one singl
band of α_2-globulin mobility. Immunoelectrophoresis revealed only one precipitin line.
When P_3 was filtered on Sephadex G 100, an act
antigen was detected in the A region; the rela
ship of this to the P_1 antigen is still being
investigated. Physicochemical analysis showed
that the purest isolated fraction contained 6%
hexoses; its activity was destroyed by chymotr
but left unaltered by trypsin, ribonuclease ar
heating. Ultracentrifugation gave a sedimenta
constant of 1.83 Svedberg U. A highly-conc.,
highly-active product, which probably represen
the autoantigen in a highly purified state, wa
isolated from the cancerous gastric mucosa. T
substance was of small molecular wt. and almos
entirely protein in nature (only 6% hexoses we
detected); it is thus comparable to the antige
characterized in experimental encephalomyeliti
in guinea pigs. Gel filtration of nonlyophili
unfractionated extracts of normal gastric muc
yielded a product having the same immunologica
specificity as the pure product; this was evid
against denaturation during fractionation. Co
parison between the fractions obtained from
normal and tumorous mucosa showed complete ide
as demonstrated by electrophoretic and immunoelectrophoretic studies. With material from
normal mucosa it was impossible to attain the
level of purity of the tumor material. It was
chemically shown that the antigen isolated fr
normal gastric mucosa was different from the

rosomal antigen reacting with autoantibodies
pernicious anemia sera. As a hypothetical
nanism for the autoantigenicity of a normal
ponent, it was assumed that substances normally
uestered within the cell are liberated into
blood stream, thus causing formation of auto-
ibodies.

2 LACTIC, PYRUVIC, CITRIC, AND URIC ACID AND UREA CONTENT OF HUMAN GASTRIC JUICE.
) Piper, D. W. (U. Sydney, Australia), B. H.
ton and L. R. Goodman. Gastroenterology
1):42-48, 1967.

conc. and output of lactic, pyruvic, citric
uric acids and urea were studied before and
er histamine (submax.) stimulation in a series
control subjects and patients with gastric
er, duodenal ulcer and gastric carcinoma.
tric carcinoma patients had a higher lactic
d conc. in basal and stimulated gastric juice
a higher lactic acid output in basal secretion
n controls and patients with gastric and
denal ulcer. Gastric ulcer patients had a
er conc. of pyruvic acid in stimulated secre-
n than controls and other patients; the output
stimulated secretion was less in gastric ulcer
ients than in controls and duodenal ulcer
ients. Basal conc. and output were similar in
4 groups except those with duodenal ulcer,
had a lower conc. than gastric carcinoma
ients. Gastric ulcer patients had a lower
al conc. of citric acid than controls and
er patients, and a lower basal output than
trols and duodenal ulcer patients. In the
mulated secretion, gastric ulcer patients had
er citric acid conc. than duodenal ulcer and
tric carcinoma patients. Basal uric acid secre-
on was less in gastric ulcer patients than in
trols; in stimulated secretion, the conc. was
her in carcinoma patients than in duodenal
cer and gastric ulcer patients and the output
less in gastric ulcer patients than controls.
sal output of urea was higher in controls than
gastric ulcer and duodenal ulcer patients. In
imulated secretion, the conc. was lower in duo-
nal ulcer patients than in controls and gastric
rcinoma patients, and the output was higher in
trols than in gastric ulcer and gastric carcino-
patients. There was no correlation of the lac-
c, citric, pyruvic, and uric acid and urea conc.
gastric juice with acid conc. After max. hista-
ne stimulation (in 7 duodenal ulcer patients and
controls), lactic acid conc. and output fell,
ruvic acid conc. and output rose, and citric acid
nc. fell and output rose. The uric acid conc.
d output varied, and the urea conc. fell and
tput varied.

73 ANATOMICAL AND SURGICAL STUDY OF THE ESOPHAGEAL-ABDOMINAL VAGUS. (It.)
ssi, R. (U. Milan, Italy), S. Salvaneschi and
Tajana. Arch. Ital. Chir. 92(5):648-658, 1966.

autopsy study of the number, position, form,
mensions and subdivisions of the esophageal-
dominal vagus nerve in 68 patients, aged 24-87, showed 2 clearly individualized trunks, 1 anterior, 1 posterior, in only 44 cases (64.5%), while multiple anterior and posterior trunks, originating as subdivisions of the 2 principal trunks or arising from plexiform formations, were found in 24 of 68 (35.5%). The positions of the principal trunks were extremely variable, as were their forms and diameters and the points at which the hepatic, gastric and celiac branches left the principal trunk. In 9 of 24 cases in which the principal trunks were multiple, no hepatic branch could be found. It is concluded that total abdominal vagotomy is the procedure of choice for inducing gastric vagal denervation.

8174 RELEASE OF HISTAMINE INTO GASTRIC VENOUS BLOOD FOLLOWING INJURY BY ACETIC OR SALICYLIC ACID. (E.) Johnson, L. R. (U. Michigan, Ann Arbor) and B. F. Overholt. Gastroenterology 52(3):505-509, 1967.

The stomachs of anesthetized dogs were filled with 154 mM NaCl, 100 mM HCl, 100 mM acetic acid, or 20 mM salicylic acid in 100 mM HCl. Gastric venous and femoral arterial blood samples were taken at various intervals for the next 120 min. and their histamine content was determined. Within 5 min. there was a significant increase in the histamine conc. of the blood draining the stomachs filled with acetic acid. A similar increase occurred within 10 min. in the blood from the salicylic acid-treated stomachs. Femoral arterial samples taken concurrently with the gastric venous samples containing the peak amounts of histamine contained little or no histamine. In no experiment was an increase in histamine detected in blood from a stomach containing NaCl or HCl. Histamine always appeared early in the salicylic and acetic acid irrigation soln. and reached peak conc. at 15 min. Histamine was usually absent from the NaCl soln. until 1 hr. of irrigation had elapsed, and then the conc. reached were low. It is concluded that the increased amount of histamine in the gastric venous blood during injury is proof that it is released into the mucosal interstitial fluid, where it can exert its characteristic physiological actions.

8175 SEASONAL VARIATION OF CONGENITAL HYPERTROPHIC PYLORIC STENOSIS. (E.) Kwok, R. H. (Nat. Biomed. Res. Found., Silver Spring, Md.) and G. Avery. J. Pediat. 70(6): 963-965, 1967.

Subjects were 248 patients admitted to a childrens' hospital over a 6-yr. period. Admissions were most numerous in April-May and October-November. The elevated incidence in Spring and Fall was statistically significant compared with Summer or Winter. Neither Spring and Fall nor Winter and Summer were significantly different from one another. There was no relationship between seasonal birth and rate of admission. Further regional studies are suggested

8176 ELIMINATION OF ROUTINE NASOGASTRIC DECOMPRESSION FOLLOWING VAGOTOMY-ANTRECTOMY AND VAGOTOMY WITH PYLOROPLASTY OR GASTROENTEROSTOMY. (E.) Herrington, J. L., Jr. (Vanderbilt U. Med. Ctr., Nashville, Tenn.). Amer. Surg. 33(5):361-364, 1967.

In 275 operations for definitive treatment of complications of duodenal ulcer, routine postoperative gastric decompression was not performed. Decompression was used only if circumstances at operation required it; suction was immediately instituted if postoperative complications developed. Surgical procedures were: vagotomy-antrectomy, Billroth I (183), Billroth II (6); vagotomy-pyloroplasty (81); vagotomy-gastroenterostomy (5). Of the 275, 246 (90%) were elective procedures, the rest emergencies. In 227 (83%) postoperative gastric decompression was not used, and patients fared well; in the rest, decompression was a vital adjunct to recovery. Of the 227 not requiring suction, 214 (94%) were undergoing elective surgery; of the remaining 13, all of whom sought early surgical treatment, 7 had acute ulcer perforation, 6 massive bleeding. Of 48 who required postoperative suction, 32 (67%) were elective cases. Of these, 4 were operated on late (more than 12 hr.) after ulcer perforation; gastric spillage and ileus were pronounced at operation, and suction was considered necessary. Of the other 44 requiring suction, 4 bled from fresh gastric suture lines during early postoperative period; 11 developed early abdominal distention; 15 required a technically difficult initial operative procedure; 14 underwent definitive operation for massive bleeding. Postoperative decompression was employed in 32 of 246 (13%) elective cases. Of 29 emergency cases, suction was used and played a vital role in recovery in 16 (55%). Postoperative suction was used in 49 of 300 (16%) patients treated for duodenal ulcer. It is concluded that postoperative gastric decompression should be performed only when definitely indicated.

8177 VAGUS REGENERATION IN THE DOG. (E.) Jefferson, N. C. (Michael Reese Hosp., Chicago, Ill.), A. Geisel, P. Lott, Jr. and H. Necheles. Surgery 61(5):808-811, 1967.

The chests of mongrel dogs were opened, 2-3 cm of each branch of the vagus nerves was resected; ends were tied with silk, and small nerve filaments were sectioned similarly. Up to 2 yr. after vagotomy fasted dogs were anesthetized, vagi were exposed in the neck, sectioned, and electrodes placed on the peripheral ends; tubes passed p.o. into the esophagus and stomach registered motility; peripheral ends of the vagus nerves, well above and below the section were stimulated, while gastric and esophageal motility were recorded. Tube position was verified at autopsy. In a number of dogs, fibers were seen originating from above the tie at the central end of the vagus and running to the peripheral end. Tissue sections were taken above, between and below the cut vagus nerves and stained with hematoxylin and eosin and myelin stains. At 1 and 3.5 mo. no functional recovery of the vagus nerves, as indicated by the absence of contract upon stimulation of the peripheral ends of the cut vagi, was observed. Of 8 observed at 12-21 mo., 7 displayed distinct gastric contractions height between 3-50 cm H2O. Distinct nerve branches were seen between the cut ends of the in these 7. Gastric motor response varied with time elapsed since vagotomy. In another series of 20 vagotomized dogs, no visible regenerated nerve fibers were observed within 1 yr.

8178 THE DUODENAL SPREAD OF GASTRIC CARCIN (E.) Paramanandhan, T. L. (U. Singap Brit. J. Surg. 54(3):169-174, 1967.

Necropsy material was from 29 patients (22 men, 7 women; 17-82 yr. at death), with gastric prim carcinoma, none with previous gastric resection The site of the primary gastric carcinoma was: cardia and fundus (13.9%); lesser curvature (27.6%); greater curvature (3.5%); pyloric antr and canal (34.5%); whole stomach (20.7%). All 26 showed invasion of the serosa, were Grade 3-adenocarcinomas (Broders) and had lymph node involvement. In 24, the subpyloric group of lymph nodes was involved and in 20 of these, the duodenum was involved. One showed invasion of the veins in both the stomach and proximal duodenum. Three of 29 (10%) showed macroscopic invasion of the duodenum, with wrinkled duodena mucosa and no sharp distinction between duodena and gastric mucosa. Microscopic duodenal invas was seen in 20 (69%), with mucosa and submucosa usually involved. In all cases of pyloric carcinoma, there was some lymphocytic infiltration of the duodenum, which could be interpreted as representing stasis produced by proximal permeation of malignant cells. In 17, invasion of th duodenum occurred chiefly through the lymphatic in 3, by direct infiltration of sheets of anaplastic cells. Surface epithelium and Brunner' glands seemed to be resistant. Tumor spread wa more marked along the lesser curvature than the greater, although in most cases the primary tum was along the line of the lesser curvature. In a few cases where the tumor was only along the greater curvature, there was no invasion of duodenum. Involvement of duodenal layers was: submucosa only, 2; muscularis only, 1; serosa only, 2; mucosa and submucosa, 2; mucosa, submucosa, muscularis, 1; submucosa and serosa, 8; muscularis and serosa, 1; all layers, 3. When serosa was involved, invasion was generally extensive. Extent of spread was 0.5-22.6 cm. In 11, there was no tumor beyond the first 3 cm of duodenum. In contrast to earlier studies, i is concluded that gastric lesions do invade the duodenum.

8179 CHILDHOOD PERNICIOUS ANEMIA. GASTROINTESTINAL SECRETORY, HISTOLOGICAL, AND ELECTRON MICROSCOPIC ASPECTS. (E.) Lillibridge, C. B. (U. Washington, Seattle), L. Brandborg and C. E. Rubin. Gastroenterology 52(5):792-809, 1967.

secretion of acid, pepsin, and intrinsic
or was studied in 9 children with true juvenile
icious anemia, 6 with Imerslund's syndrome,
3 with pernicious anemia associated with
ric atrophy. Biopsies of gastric mucosa were
ied by light and electron microscopy. Secre-
of intrinsic factor was low in juvenile
icious anemia and atrophy-associated anemia,
was normal to moderately reduced in those with
slund's syndrome. By the authors' examina-
, acid secretion was normal during periods
dequate vitamin B_{12} therapy, both in juvenile
icious anemia and Imerslund's syndrome. The
ory of those patients showed that during
ods of vitamin B_{12} deficiency, histamine
achlorhydria (not augmented) was frequent.
ric biopsies appeared normal in the juvenile
icious anemia and Imerslund's syndrome patients,
revealed gastric atrophy in all 3 having
lorhydria despite their adequate vitamin B_{12}
lacement. No fine structural abnormalities
detected with the electron microscope. The
rapeutic status correlated poorly with histo-
ical data. Duodenojejunal biopsies appeared
mal although vitamin B_{12} malabsorption had
n demonstrated in Imerslund's syndrome. It is
cluded that the data offer no certain explana-
n of the pathogenesis of gastric atrophy in
nicious anemia of adults.

0 CLINICAL FAILURES IN DIAGNOSIS OF GASTRIC CANCER. (Rus. Nartsissov, T. V.
d. Inst., Gorky, USSR). Vop. Onkol. 12(10):
97, 1966.

ing a 15-yr. period (1946-1960), an error of
gnosis was made in 142 (4.83%) of 2963 pa-
nts (1661 men, 1302 women; 87 of whom were
s than 31 yr. old, 942 were 41-50 yr. old and
7 were 51-60 yr. old) treated surgically for
tric cancer. The greatest percentage of
gnostic error (12.7%) among patients younger
n 31 yr. of age was due to a mild or asympto-
ic course of the disease in its initial stages
a markedly less pronounced disturbance of the
neral condition. The stage of the disease also
fluenced the frequency of error, i.e., the
eatest percentages of diagnostic error were
und in Stages 1 (21.1%) and 2 (6.5%). The
cation o the neoplasm was also important, i.e.,
en located in the distal stomach, diagnostic
ror was 5%; in the gastric body the error was
4%; in the proximal stomach it was 2.5% and
e error for total lesions was 2.0%. In 85%
the patients gastric cancer was mistaken for
rious surgical diseases of the stomach; the
agnostic error for ulcer was 53.5%, for tumors
the abdominal cavity it was 9.2% and for
cute stomach" it was 9.9%. Pain symptomatology
s similar in both cancer patients which were
correctly diagnosed and in controls (148 pa-
ents with a correct diagnosis). Various fac-
rs leading to incorrect diagnosis were an
sence of wt. loss, postcibal epigastric pain,
long history of gastric complaints, other
stric diseases such as ulcer, polyposis and
stritis, and associated diseases such as rheu-
tism, cholecystitis and nephritis. Many
objective symptoms occurred just as frequently in both the control group and in those indirectly diagnosed; however, other symptoms which occurred less frequently in the incorrectly diagnosed group included achlorhydria and tumor palpability, while those which occurred more frequently in the controls included fever. In 89.5% of 125 in the incorrectly-diagnosed group, the patient's radiologist had not recognized malignant tissue, and no X-ray was made in 17. Gastric cancer is most frequently mistaken for ulcer (39.2%), and in 9.6% it was mistaken for polyposis. A distorted clinical picture of gastric cancer was found in 11.6% of the patients. Analysis of the clinical-radiological symptoms revealed that gastric cancer diagnosis could be made in 50; gastric cancer symptoms were present in 79; only in 7 were they not observed and in 6 gastric symptomatology was absent.

8181 GASTRIC SECRETORY FUNCTION DURING CHRONIC INTOXICATION WITH GRANOSAN. (Rus.) Ostapenko, O. F. (Kirgiz Med. Inst., Frunze, USSR). Sovet. Med. 29(11):70-73, 1966.

In 41 patients functional disturbances of gastric secretion were already evident during the early period of chronic intoxication with Granosan (ethyl mercuric chloride); the disturbance was characterized by a decrease of reflex secretion and an increase in the neurochemical phase of secretion. Hyperacidity was present in 22 of the patients, and normo- or hypoacidity in the others. An inert type of gastric secretion was found in 31, an asthenic type in 3, inhibitory in 3, isosecretory in 2 and normal in 2. The quantity of gastric juice was increased (125-300 ml) in 30, decreased in 7 and normal in 4. Two patients exhibited a positive reaction to lactic acid. A large amount of WBC and epithelial cells were found in the gastric sediment of 28 patients. The av. total gastric acidity was 64.7 titer U, and that of free HCl was 42.4. Both were decreased in 16 patients, chiefly during the first phase of gastric secretion. In 18 patients studied at a later period (1-3.5 yr. after appearance of the initial symptoms of intoxication) there was inhibition of the reflex and neurochemical phases of secretion, with a significant reduction in the amount of total and free HCl. The quantity of gastric juice on an empty stomach at an early period was 121 ml, and at a later period it was 52.1 ml; hourly stress yielded 99.7 ml during the early period and 54.5 ml at a later period. The av. amount of total HCl decreased from 69.6 to 44.4 titration U and that of free HCl decreased from 50.6 to 23.9 titration U. In 8 patients, in spite of a decrease in secretion, the total gastric juice acidity varied from 66-82 titration U, and the amount of free HCl from 45-68 titration U. Gastric analysis revealed a large amount of mucus, epithelial cells and segmented-nuclear WBC. Inhibitory and isosecretory types of gastric secretion were increased. These changes probably reflect disturbances of the regulation of secretion by the higher centers of the central nervous system; the local toxic action of Granosan is not excluded.

8182 THE MORBIDITY OF GASTRIC CANCER IN MINSK (1962-1964). (Rus.)

Skoblia, E. S. (Oncol. Dispensary, Minsk, Byelorussian SSR). Vop. Onkol. 12(9):110-111, 1966.

During the period 1962-1964, a diagnosis of gastric cancer was made in 735 (av. 37.6/100,000 population) patients (whose age ranged from less than 29 yr. to over 70) in Minsk; this figure represents 30.1% of all cancers diagnosed. Morbidity per 100,000 was 37.1 for women and 36.4 for men. A study of 719 patients revealed no difference according to age and sex, i.e., males formed 45% and females 55% of the total, and 87.3% of the females and 70.6% of the males were over 50 yr. of age. There was a yearly increase in gastric cancer morbidity, i.e., in 1962, 62.3% and in 1964, 72.5% of the total number recorded with such a diagnosis. The largest percentage of patients in a second clinical group (74.5%) was in the age range of 40-59 yr., while of those over 70 yr. of age, 59% were curable. Of those in the second clinical group, 26.4% were not treated. Those gastric cancer patients in whom the diagnosis was made at postmortem examination represented 8% of the total number of gastric cancer patients registered in 1962-1964; most of them were either less than 35 or more than 60 yr. of age. Of 719 patients, 305 (42.4%) were operated upon; surgery was radical in 176 (24.5% of all patients or 57.7% of all those treated surgically). Operability of gastric cancer patients decreases as age increases; therefore, the best treatment is dependent upon an early diagnosis of gastric cancer.

8183 COMPARATIVE ESTIMATION OF STOMACH RESECTIONS WITH GASTRODUODENO- AND GASTROJEJUNOANASTOMOSIS IN CANCER PATIENTS. (Rus.)

Kravets, B. B. (Regional Oncol. Dispensary, Voronezh, USSR). Vop. Onkol. 12(10):9-16, 1966.

In the Voronezh regional oncologic dispensary, from 1956-1964, 209 (187 of which were for cancer of the distal stomach) gastric resections with gastroduodenoanastomosis (Billroth I) and 239 (186 of which were for cancer of the distal stomach) with gastrojejunoanastomosis (Billroth II) were performed. Most of the patients with the Billroth II procedure were 50-60 yr. old, and those who had Billroth I were 60-70 yr. old. A total of 139 of those with Billroth I and 135 of those with Billroth II had a subtotal and high resection; the resp. values for gastrectomy were 4 and 22, for limiting subtotal resection, 2 and 2, for combined, 35 and 27 and for palliative surgery, 7 and 0. Of 187 patients with Billroth I, lymph node metastases were present in 40.5%, tumor penetration into the gastric serosa in 82.5% and penetration into the surrounding tissue in 18%, as compared to 45%, 77% and 14.5%, resp., in 186 patients with Billroth II. A total of 6.4% of those with the Billroth I resection and 7.5% of those with the Billroth II resection had Stage I cancer; the resp. values of those who had Stage II cancer were 5.3% and 11.8%, for those with Stage III, 84.6% and 80.7% and Stage IV, 3 and 0%. Of 187 patients with Billroth I, 33.1% had exophytic, 5.3% transitional and 61.5% endophytic growth, while the resp. values for 186 patients with Billroth II were 35%, 15% and 50% Postsurgical complications were found in 11.2% those with Billroth I and 9.7% of those with Billroth II procedures. Faulty anastomotic sut were found in 2.4% of the patients with the Billroth I (all in an advanced stage, and 80% with endophytic growth), and 1 of which was cur faulty sutures were found in 2.15% of the patie with Billroth II (all Stage III, 75% with exoph growth). Total mortality after Billroth I was 4.8% and after Billroth II it was 4.3%. A fata outcome due to peritonitis with or without faul sutures of anastomosis for those with Billroth was found in 2.14% or 1.07%, resp.; for those with Billroth II, the resp. values were 2.16% o 1.08%. The higher degree of fatality among tho with Billroth I procedures (9 patients) as compared to those with Billroth II procedures (8 patients) was due to advanced age (73% were over 60 yr.), endophytic growth (in 7 of 9) and the advanced stage (4 of 9 were Stage IV). Excluding one patient who died from carcinomatous cachexia and intoxication, the postsurgical mortality for the Billroth I group and Billroth II group was 4.27 and 4.34%, resp. Of 51 patients with Billroth I procedure, 45 were followed-up for 5 or more yr., and 217 of 231 patients with the Billroth II procedure were observed for the same length of time. Of those in the Billroth I group, 31.4% of those operate upon or 35.5% of those followed, survived for 5 or more yr.; the resp. values for those of th Billroth II group were 31.6% or 33.6%. The best results for those with Stage I cancer were obtained with the Billroth I procedure (71.4% of those with a Billroth I survived for 5 or more yr., compared to 61.5% of those with Billroth I The results for Stages II and III of cancer wer almost identical for both types of operative procedure. Problems of evacuation occurred mor frequently with the Billroth II (2 patients) procedure than with the Billroth I (no patients) It is concluded that Billroth I is at least as effective as Billroth II, and in some cases it was even more effective.

8184 MOTOR-SECRETORY FUNCTION OF THE STOMAC IN EUTHYROIDAL AND TOXIC GOITER. (Rus

Khoromskii, L. N. (Med. Inst., Ternopol, USSR). Probl. Endokr. Gormonoter. 12(6):27-30, 1966.

Of 12 patients with a euthyroid goiter, 4 had disturbances of gastric contraction before surgery (in 3, disturbances were hypokinetic in nature; in 1, they were stimulatory), but 5-7 mo after thyroid surgery no basic changes in gastri motor function were noted and in most patients contractions were normal. In 22 of 39 patients with toxic goiter, either gastric contractions were completely absent during the entire period observation or single arrhythmic contractions of

force of 0.5-1.0 cm H_2O were found; 15 of 39 had
tractions of hypokinetic nature with a force of
cm H_2O. At 5-7 mo. after surgery, gastric motor
ction had returned to normal in 50% of the
ients. In several patients gastric motor func-
n improved but contractions remained hypo-
etic in nature. Only 2 patients exhibited
nesia, compared with 22 before surgery. Thus
tric motor function was inhibited in patients
h toxic goiter. Inhibition of gastric con-
ction was more pronounced in patients with
nounced thyrotoxicosis. In patients with
hyroid goiter, the shifts in gastric motor
ction were much less pronounced. Decrease in
tric muscular tonus was more pronounced in
ients with toxic goiter. In the latter, normal
dings were evident in only 20% of the patients,
6 mo. after surgery 50% had normal values.
dity of gastric juice was approx. 50% of normal
ore surgery in 31 of 39 patients, and was
malized in 50% of the patients 6 mo. after
gery. Acidity of gastric juice remained normal
patients with euthyroid goiter. Various tonics,
h as a 10% soln. of NaCl, Vitamins B_1 and B_{12},
gastric juice, stimulated peristaltic and
ic contractions and increased gastric tonus
0 min. after they had been admin. i.v., i.m.
into the gastric cavity, resp.; NaCl was the
t active and gastric juice was the least active.

35 PATHOLOGICAL CONDITIONS OCCURRING AT LATER PERIODS AFTER GASTRECTOMY. (Rus.)
okhvalov, V. I. Vestn. Khir. Grekov. 97(11):
-88, 1966.

thological conditions occurring within 18 yr.
ter Billroth II gastrectomy for peptic ulcer
06), polyposis (63) and cancer (72) were studied
a total of 741 patients. The dumping syndrome,
rying in severity, was found after 3 yr. in 224
741 (30.2%), after 5 yr. in 191 of 603 (31.6%),
ter 10 yr. in 77 of 235 (32.7%) and after 15 yr.
22 of 67 (32%). The resp. values for the late
poglycemic syndrome were 0.9%, 1.0%, 2.0% and
0%; for the afferent loop syndrome of variable
gree of severity, these values were 9.0%, 10.0%,
.0% and 14.0% of the observed persons. The
all stomach syndrome, found in 14 of 741 (2%),
rsisted for 3-13 yr. after surgery. A moderate-
